DIRECT UNITED STATES CABLE COMPANY.—At a meeting of the Board of the Direct United States Company, held on the 8th inst., it was resolved to recommend a final dividend of two shillings per share, free of income tax, such dividend to be payable on and after the 30th inst., making, with the interim dividends already paid, 2 per cent. for the year ending 30th June last. Recourse will be had to the interest on the reserve fund to make up the required amount for such dividend. The transfer books will be closed from the 15th to the 29th July, both days inclusive.

FAURE ELECTRIC ACCUMULATOR COMPANY. — Messrs. Francis Cooper and Herbert Canning, the liquidators of the Faure Electric Accumulator Company (Limited), notify that they are prepared to pay a dividend of 20s. in the pound to the creditors of the Company, on application at the offices of Messrs. Cooper Brothers and Co.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.—Notice is given that a half-yearly general meeting of this company will be held at the Cannon-street Hotel, London, on Thursday, the 19th instant, at 12 o'clock noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income tax. The company's share register will be closed from the 12th to the 20th inst., both days included.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 8th inst. were £3,154, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NOTES.

HAMBURG.—The telephone line between this city and Berlin has now been opened for the public service; the distance is 150 miles. We hope shortly to give further details as to this line.

KIMBERLEY.—During the Jubilee celebrations at Kimberley, South Africa, Mr. Cousens, the manager of the local electric lighting company, carried out a number of very successful illuminations with incandescent lamps of varied colours.

BARNSLEY.—The premises of the "British Co-operative Society" have been fitted with electric lighting plant by the firm of Wilson Hartnell, of Leeds. The installation consists of a 450-light Crompton compound self-regulating machine, and, at present, about 220 sixteen candle-power Edison-Swan lamps. The dynamo is driven from the main engine, which is employed in the building.

THE TELEGRAPH IN 1857.—*The Times*, referring to the gigantic task undertaken by Mr. Samuel Palmer in compiling an abstract of the history recorded in its columns, mentions that in the description which appeared in its columns of the Great Exhibition of 1851, in the section devoted to railways the telegraph is referred to eight times only, while the word "telegram" had not as yet been coined.

EXETER.—The Western Counties and South Wales Telephone Company opened an exchange at Exeter on the 27th ult. with about a dozen subscribers. The rates charged within a one mile radius are for one year's subscription £12 per annum, for four years' agreement £11 per annum, for seven years agreement £10 per annum. It is hoped shortly to extend trunk wires to some of the neighbouring towns.

ELECTRIC TRAMWAYS.—The electric tramcars have not been running at Brussels for some days, owing to an accident to the machinery at the charging station. It is a great pity that this plant has not been duplicated.—Rumour has it that a similar consequence on a line nearer home is due to a similar cause, but on this matter we shall probably before long have more to say.—A tram line to be worked by electricity is being laid out between Bilbao and Sauturce.

PROPOSED ELECTRIC LIGHTING AT GOVANHILL.—Last Tuesday, at a meeting of the Police Commissioners of Govanhill, one of the Glasgow suburbs, a minute of the Lighting and Cleansing Committee was submitted in regard to a proposal to adopt electric lighting for the street lamps. A contractor had offered to fit up each lamp complete at a cost of 16s.; and the cost of a light of 8 candle-power in each lamp would be 12s., and one of 16 candle-power 24s. per annum. The decision was adjourned for further consideration.

"THE WESTERN ELECTRICIAN."—When such tremendously rapid progress is being made in the American States in the practical application of electricity it is not surprising to find that the roll of technical journals has been lengthened by the advent of the *Western Electrician*. Our new contemporary hails from Chicago, and is to be published weekly on Saturdays. The first number is calculated to give a very favourable impression, the articles throughout being of a description which should appeal forcibly to the class for whom the journal is intended.

TEMPORARY LIGHTING.—The United Electrical Engineering Company recently carried out a temporary installation of 15 arc lamps and 30 incandescents at Walham Green in connection with the Butchers' *fête*. In previous years this particular event has unfortunately been associated (in other hands) with rather unfortunate exhibitions of electric lighting freaks. On the present occasion special care was taken to avoid any possibility of mishap, and a spare dynamo was placed in position, although it was not needed. The committee expressed themselves highly satisfied with the result.

OVERHEAD WIRES IN MEXICO.—According to advices of June 25th, from the City of Mexico, steps are being taken to remedy the cause of so many complaints respecting the dangers and inconvenience of overhead wires in that city. The representatives of the electric light, telephone, and telegraph companies of the city have had a conference with a committee of the Municipal Council at which a proposition was agreed to in favour of the erection of posts sufficiently large to carry all the wires of all the companies, on the system carried out in New Orleans by Colonel Flad. If the proposal is confirmed, the city council will proceed to the construction and erection of the posts, and will charge a moderate rental to the companies.

THE REPORTED INJURY TO VEGETATION BY ARC LIGHTS AT ST. PETERSBURG.—At a meeting of the Electro-Technical Society of Berlin, Herr Arnold Siemens took occasion to contradict the report that the tropical plants in the Winter Palace at St. Petersburg had received any injury from the electric light. The damage was entirely due in his opinion to the way in which the plants had been removed from the hot-houses upon a night of great cold, and without sufficient protection. He had also learnt that these particular plants remained without attention for three weeks subsequently, and the blame was then thrown on the electric light. We are very pleased to have this contradiction of a report to which it was difficult at any time to give full credence.

JEHL AND RUPP'S FARADAY DISC DYNAMO.—In another column will be found a further description of the mode of constructing the armature of the interesting disc machine by Jehl and Rupp, which was described and illustrated in a recent issue. The Faraday disc experiment has already been taken as the basis of designs for dynamos by several inventors; amongst others may be named Edison, Sir Wm. Thomson, Bollman, and one form of the Elphinston-Vincent, but none of these machines, so far as we are aware, have hitherto achieved practical success. The merit of the present design consists in the very ingenious way in which the particular shape of the coils and polar faces which will give the maximum E.M.F. per revolution with least waste of space has been determined.

OPENING OF TELEPHONIC COMMUNICATION BETWEEN GLOUCESTER AND BRISTOL.—The Western Counties and South Wales Telephone Company have opened telephonic communication between Bristol and Gloucester. The trunk line from Gloucester extends to Sharpness Docks, where it joins the lines connecting Bristol with Cardiff. At the formal opening the Mayor of Gloucester delivered a speech through the telephone to Bristol, and Mr. Lewis (the general manager and secretary of the company) gave some interesting information as to the present extent of the company's business and their hopes for the future with regard to the extension of trunk lines. The company will very shortly have at work 282 miles of poles and 865 miles of wire in their trunk lines alone.

ST. BRIDE'S CHURCH, FLEET STREET, STRUCK BY LIGHTNING.—During the brief thunderstorm which burst over the metropolis on Friday last, the Church of St. Bride's, in Fleet-street, was struck by lightning. An eye-witness describes the appearance of an immense ball of a dark silver colour which descended the conductor. Fortunately the damage done to

Digitized by Google

the steeple was very slight, a few loose stones were displaced from the belfry, and at the point where the conductor enters the ground the earth was slightly disturbed. Considering the long spell of dry weather, this speaks fairly well for the earth connection of the conductor. Some injury was done to the telephone and telegraph instruments in the immediate neighbourhood; amongst others the magneto-bell coils of our own telephone were fused.

THE "WATER BATTERY."—M. D'Humy has at length placed in the market his "water battery," about which various mysterious rumours have from time to time been circulated. The cell is made up of iron and carbon, but the carbon is constructed in the form of a narrow rectangular box, and this is filled with nitric acid. Pure water is poured into the outer cell, in which the iron plate and carbon box are placed. The percolation, or endosmose of the acid through the carbon, is, we believe, supposed to add considerably to the E.M.F. of the cell. The *Investors' Guardian* is of opinion that "this is a very important matter for the consideration of shareholders, and, in fact, of everybody having anything to do with gas companies," even, we suppose, down to the lamplighters. We observe that our worthy contemporary describes M. D'Humy as the "inventor of the Water Primary Battery Company (Limited)."

ELECTRICITY APPLIED TO LINE FISHING.—The true sportsman will certainly scout the idea that electricity can possibly lay claim to any legitimate share in the placid delights of the disciples of rod and line. It may possibly, however, be necessary to remind him that fly-fishing is not the only method of pursuing the business. Float fishing, although undeniably the very laziest kind of "sport" under the sun, is still followed, and such being the case there can be little doubt that its devotees will welcome any development which still further diminishes the necessity for any exertion in the pursuit of their ignoble art. The only room for improvement in this direction appears to lie in the possibility of rendering it unnecessary for the fisherman to keep his eye upon the float. For this end an arrangement has been devised whereby a pull upon the line closes the circuit of a tiny battery carried in the base of the rod, and this is made either to sound an alarm or to gently tickle the hand of the fisherman as he grasps the butt. The sport has thus been brought to a state of the highest perfection, for nothing now hinders him from going comfortably to sleep.

SHERLOCK'S TELL-TALE TELEGRAPH FOR STEAMSHIPS.—This is an automatic tell-tale, placed in the engine room of ships, and arranged so that should the engineer in charge misread the indication given on the ordinary telegraph dial, or should he move over the reversing link contrary to orders, an electric alarm would be set ringing, and would continue to ring until the mistake was rectified. This is done by means of a contact plate capable of moving in a vertical direction and controlled by the movement of the reversing lever. This plate has a hole in its centre, into which projects an insulated point fixed on a plate whose circular movement is worked from the finger on the dial in the engine room. When an order is signalled by the officer in charge, and is recorded on the dial in the engine room, the contact point is moved round, and if the order is fulfilled the contact plate is necessarily moved in the same direction as the point; but should the reversing lever be moved in the opposite direction, then the plate also moves in the opposite direction, thus closing an electrical circuit through the point and ringing a bell. The apparatus is made by Messrs. Johnson and Phillips, of London.

POSTAL AND TELEGRAPH REFORM.—A meeting of members of Parliament was held yesterday week for the purpose of forming an association for cheapening and extending the postal and telegraphic facilities of the Empire. Mr. Henniker Heaton was elected chairman. After a discussion, the following resolutions were carried:—1. That the postal and telegraphic communication between England and all other parts of the Empire is unsatisfactory, and therefore detrimental to British interests. 2. That a Parliamentary Committee be formed for the purpose of cheapening and extending the postal and telegraphic facilities of the British Empire. 3. That meetings of the committee be held from time to time to decide on the action to be taken for advancing the object in view. 4. That Mr. Henniker Heaton and Mr. H. L. W. Lawson be appointed joint hon. secretaries of the committee. Ninety-six members of Parliament had their names enrolled on the committee. The first steps to be taken were discussed at some length. A large public meeting will probably be held soon, and the Government will be invited to appoint a Select Committee of the House of Commons to examine into the question.

THE JUBILEE OF THE TELEGRAPH.—The arrangements for the dinner in the Holborn Restaurant on the 27th inst., in connection with the Jubilee of the Telegraph are now practically complete. The general committee met again on Tuesday at the offices of the Society of Telegraph-Engineers, when the programme was finally discussed and agreed upon. Covers will be laid for about 240 gentlemen, and amongst the speakers will be the Right Hon. Cecil Raikes, M.P. (chairman); Mr. Edwin Clark, Mr. John Pender, Sir Wm. Thomson, Sir Lyon Playfair, M.P.; Prof. Stokes, Sir Frederick Bramwell, Mr. Shaw Lefevre, M.P.; Mr. Bruce (President of the Society of Civil Engineers), Sir Charles Bright, Sir Algernon Borthwick, M.P., &c. The sub-committee who were entrusted to make the arrangements have been most indefatigable in their labours, and have left no stone unturned to provide an entertainment worthy of so important an event. It need be no secret that, in their anxiety to do so, the gentlemen composing it, with a few of their friends, very pleasantly rehearsed some of the effects that may be expected on the 27th by dining together in the Holborn Restaurant according to the *menu* which has been fixed upon for the occasion.

SERIOUS FIRE IN THE FACTORY OF THE UNITED STATES ELECTRIC LIGHTING COMPANY.—A fire broke out in the incandescent department of the great factory of the United States Electric Lighting Company, at Newark, N. J., Friday afternoon, June 17th, and destroyed the property of the company to the amount of probably $250,000, which is, however, covered by insurance. Fortunately, all the general machine shops, laboratory, dynamo and arc lamp departments, engines, boilers, etc., were saved, the fire being confined to the south side of the immense works. The incandescent department was entirely consumed, also the office, the stock department, and glass blowing and lamp exhausting departments. The cause of the fire is supposed to have been from a gas leak or from spontaneous combustion resulting from waste. There was no electric current in the room where the fire originated. The fire burnt very rapidly, the walls falling in fifteen minutes after it was noticed. Over 300 employés are thrown out of work. A temporary factory for the manufacture of lamps has been arranged for. The company recently purchased a tract of land adjoining for the purpose of increasing factory facilities, and will now build on a very much larger scale.

THE LIGHTING OF THE BRIGHTON PAVILION.—The latest chapter in the chequered history of the Brighton Pavilion

Digitized by Google

installation may perhaps appear to cast some doubt upon the precise utility of calling into play the services of a consulting electrician, seeing that, as the result of the specification recently issued, the highest tender exceeds the lowest in the ratio of nearly three to one. As a matter of fact, however, it is within our knowledge that there exist certain peculiarities in this case which go far towards explaining the discrepancies. We have had a mass of information placed at our disposal in this matter, but we fail at present to see that any good end would be served by its publication. To avoid misapprehension, let us add that the circumstances referred to are solely of the nature of misunderstanding, and nothing beyond this is at all hinted at in any quarter. The results of the tenders were as follows:—Anglo-American Brush Company, Lambeth, £1,510; Marshall and Co., Liverpool, £1,325; Rashleigh Phipps and Merry, 187, Gray's Inn-road, London, £990; Nicholson and Jennings, Old Kent-road, London, £904. 10s.; Brighton Electric Light Company, £720; F. Geere Howard, Oxford-street, London, £700; Gülcher Electric Light Company, £650; Bailey and Grundy, Paddington, London, £578; and Maxim-Weston Electric Company, Queen Victoria-street, London, £525.

THE LIGHTING OF THEATRES: REPORT PRESENTED TO THE PARIS MUNICIPAL COUNCIL.—The Committee of the Paris Municipal Council which, after the disaster at the Opera Comique, was instructed to investigate the whole question of the electric lighting of theatres has presented its report, of which the following are the most important passages. We may, however, premise that the Municipal Council possesses no jurisdiction over the theatres which are subsidised by the State, the control of which is wholly in the hands of the police. The report is expressed in the most emphatic terms:—"To avoid fires we must suppress their cause, namely gas. Gas should be entirely prohibited under any form whatever. Install electricity. It is not for us to appear as the patrons of any one particular industry, but the results which have attended the introduction of the electric light are absolutely conclusive in this matter. We recommend, therefore, that the Council should pronounce in favour of electricity for the lighting of theatres, but without specifying any particular system; and we would add that the motive power should be placed outside the theatre, if only for the excellent reason that in the majority of theatres it is impossible to make proper provision for the plant inside the walls." The committee recommend the appointment of a special commission to consider in detail the measures of precaution to be taken for each of the municipal theatres and for the unsubsidised places of amusement. In the discussion which followed the recent action of the Prefect of Police was strongly condemned.

JUBILEE HONOURS.—The *Saturday Review*, commenting on the distribution of honours on the occasion of Her Majesty's Jubilee, considers that "it is matter for regret that the opportunity was not taken, or did not present itself, of singling out for honour the names of men who in art, in letters, and in science have given to the Victorian era a distinction not inferior to that which belongs to it in material and political development. The House of Lords is, of course, primarily an assembly of statesmen and an instrument of public business. It is not less efficient in the discharge of those functions from the fact that they are chiefly exercised by a dozen or a score of leading statesmen, while the bulk of peers are content to be hearers only. Something like this was the case with the House of Commons in its best days. But the House of Lords is something more than a legislative chamber. A peerage is the highest distinction the Queen can confer. The House of Lords would be strengthened in that public opinion on which all institutions now depend if the principle on which the barony of Lord Tennyson was conferred were more generally acted on, and it could be made representative through suitably selected types of all that is most illustrious in the national life, in letters, science, art, industry, and the various public services. The ornamental side of institutions, especially of institutions which are supposed to exhibit the qualities which England most honours, cannot safely be neglected. Quarter-Sessions and ex-President-of-the-Local-Government-Board peerages are all very well in their way; but they are scarcely sufficient to sustain or revive the reputation of the peerage as the supreme order of merit in England. It cannot be said to have this character now; but it might have it with advantage to itself and to the nation."

PROJECTED ELECTRIC LIGHTING AT MALTON.—The notice which recently appeared in our advertisement columns inviting tenders for lighting the town of Malton by electricity or otherwise resulted in no less than twenty-four applications from electrical firms for specifications and further particulars. The specifications have been prepared by Mr. J. L. Webster, the borough surveyor, and state that the lighting district extends over about ten square miles. In the case of electricity the contractor is to state whether the mains be underground or overhead, and to give the number of lamps which he proposes to employ—so many arcs of 2,000 and 1,000 candle-power, and so many incandescent lamps of 16 and 10 candle power. Tenders are to be sent in for both one and three years, and contractors are informed that "generating stations, with all necessary power, can easily be found in different parts of the borough." At the present time the public lamps are lit by the Gas Company at a rate varying between 2s. 6d. to 2s. 8d. per 1,000 cubic feet; the company also supplying the lamps and undertaking their maintenance. The total cost does not exceed £600 per annum. Private consumers are charged 3s. per 1,000 cubic feet. In this instance it is probable that the Local Board had originally no very serious intention of utilising electricity, but merely thought it would be interesting and instructive to hear what electrical engineers might have to say. This is, perhaps, advisable as a preliminary step, provided that the firms who send in tenders have reason to think it worth while on their part to go seriously into the calculations; but as things go the chances are that the affair will result in a mere repetition of the Southport episode, where—as we may state for the information of the Malton local authorities—a similar step taken by the Corporation resulted in tenders varying from a few hundreds to many thousand pounds according to the real or factitious ideas of the tenderers as to what should constitute a satisfactory installation. We have always insisted, and shall continue to insist, that it is impossible for corporations or private individuals to obtain any valid idea as to the cost of electric lighting on any large scale by inviting open tenders from all and sundry on the basis merely of specifications drawn by borough surveyors or other non-technical persons, and which, therefore, do not profess to contain more than a vague and general idea of what they would like to get. If the Malton Local Board thinks seriously of employing the electric light—and we need hardly say that if this be the case we shall be the first to congratulate them upon their enlightenment and progressive spirit—they must be prepared to disregard the discrepancies which will necessarily appear in the tenders which they have now invited. Before coming to a definite conclusion they should invite some thoroughly competent consulting electrician to prepare a careful and exact specification, upon the basis of which they may then

Digitized by Google

feel confident that the work can be carried to a perfectly successful issue.

A PRIMER MOST PRIME.—An American "Primer on Electricity," which has recently made its appearance, and is described as intended "for the use of persons whose duty it is to look after electric lighting plant," is probably intended as a scientific analogue of Señor Carolino's famous work on "English as She is Spoke." It strikes us, however, that the joke has in some cases been a little too carefully elaborated, and might conceivably lead to serious results. For instance, if the book should actually get into the hands of any member of the class referred to on the title page (which is, of course, part of the joke), it is just possible that they might take seriously such a passage as the following:—"Insulation.—Any substance, non metallic, can be used for insulation from paper up. It is the fact that no metal contact exists, and the various substances must be judged according to the work to be done." The latter sentence we do not pretend to fully understand; but we presume that the author will accept as a corollary the dictum that the work *being* done must be judged by the result, and we are really afraid that the results of this kind of joke are likely to be mischievous. However, there is a great deal of fun in the book of a perfectly harmless character, as, for instance, when concerning speed indicators we are told, "Of these there are various makes; but the best are those which will denote the exact speed." The section on electrical instruments is good. "Ammeter.—Ampere meter is an instrument for measuring the current in amperes. By its use (if in circuit) it will instantly show the condition of the current. Voltmeter.—Voltmeter is about the same, but gives the measurement in volts or E.M.F. Every installation should have these two instruments. Without them the party in charge is in the dark, however brilliant the light may be. If a breakdown occurs he is often unable to detect the cause." The section on electromotive-force is also "about the same," as will be seen from the following extract:—"Electromotive force expresses in electricity what steam in a boiler does to an engine, but as no circuit or work can be obtained without resistance, then we conclude that much E.M.F. is wasted in overcoming this resistance." A little later, to find further scope for his racy humour, the author indulges in a disquisition on short circuits:—"Short circuit means that the current takes the shortest path, and having no work to do causes fire. Moisture will cause a S. C. This will generally burn up the dynamo. Moisture leads to loss of current, and to the destruction of the conductor and the injudicious use of earth." We may appropriately conclude our comments in the words of the preface:—"These few hints may be of considerable benefit to the engineer (and being a man of good common sense), to such this work will, I hope, prove most valuable"—as an electrical Joe Miller.

ELECTRIC EELS FOR LIGHTING A RESIDENCE.—The *Electrical Review* of New York is responsible for a veracious story, of which the following is an abstract:—Don Miguel Santa Mezzito, a wealthy gentleman living in Achaguas, Venezuela, now at the Girard House, Philadelphia, alleges that he has succeeded in utilising electricity generated by electric eels, and that his residence is lighted by electricity by this means. Senor Mezzito is a well-educated man, graduated from Heidelburg University, and speaks several languages, including English, quite fluently. "Yes," said he, "I have my residence lighted throughout by electricity generated by large batteries of electric eels. There is sufficient electricity wasted in the streams of the northern portion of South America to light a city as big as Philadelphia, could it be properly utilised. The town of Achaguas lies on the bank of a small river of that name, which empties into the Orinoco 100 miles to south-east; it is in the State of Apure, about 150 miles from the eastern boundary of the United States of Columbia. The city is reached by boat up the Orinoco to San Fernando, and by rail from that place. Achaguas is an old town and has been the home of my family for many generations. I give you this in detail, because I have met scientists since I came to this country who evidently disbelieve that I have electric lights running by electric eels. I got my first idea of utilising the *gymnotus electricus* while studying electricity in Germany. Living as I had for years near streams in which eels abounded, and knowing personally of men and animals that had been prostrated and were killed by eels in water, I was especially interested in Faraday's account of the torpedo and other fishes. I was particularly impressed by the great scientist's statement that a full grown electric eel contained electricity equal to 15 Leyden jars of 3,500 square inches. Upon returning to my home I at once began experimenting, and was both surprised and delighted with my success, and after two years of further experimenting I succeeded in getting a battery by which a small light was run nearly an hour. Then it was merely a question of time and study. I have had the lights running, eight of them, eight-candle each, for three months. My success has brought me to this country, and I propose to explain my invention and discovery to the members of the Franklin Institute before I return to Venezuela. I first tried the placing of a number of the eels in one large rubber tank well insulated, but I afterwards discarded it, and tried the forming of a strong battery by the connection of fifty cells with two or more eels in each. The result was more than satisfactory. Each cell is so connected as to complete a circuit through the wires running from either end of the row to the lamps, which are all in one circuit. The only secret is the manner in which the electricity is conducted from the cells. That I believe to be an entirely original discovery, and I shall not divulge it until it is protected by patents both in Europe and America. The eel, I learned, makes heavy, involuntary discharges of electricity when its circulation is increased, or when unnaturally excited. I found it necessary to keep the eels excited in order to compel them to throw off their store of electricity steadily. I tried several ways of keeping a wheel revolving in each cell, but afterward learned that the placing of strychnine in the liquid in which they are kept accelerated circulation by producing tetanic contraction of the muscles, and did all that was required. 'How about when the store of electricity is exhausted, you ask?' Well, that is easily overcome. I do not allow a battery to work more than half an hour at a time. By a very simple clock-work contrivance I have so fixed things as to instantly, and at regular intervals, throw one battery off and another on. I keep these batteries of thirty cells each all the time ready. Relieved for an hour the eels are as active as ever. During the half hour of service the strychnia has become absorbed and the fishes quickly recover their natural power. Thirty cells of two eels each are equal to 1,000 volts. Each eel is a perfect battery within itself. There are two positive and two negative eels one-thirteenth of an inch in diameter in each cell. I keep a large tank full of the eels on hand all the time, and am compelled to replenish the batteries every day or two. I have attempted to propagate the eels, but thus far have not been successful. No; I do not see that my discovery and invention will ever benefit the world very much, because these eels are not found much outside of Northern South America, but it is interesting from a scientific standpoint, and I consider my time, labour, and money well spent."

THE FARADAY DISC MACHINE OF JEHL AND RUPP.

(FROM A CORRESPONDENT.)

In *The Electrician* of June 10th the above-named disc machine was described, and the mechanical principles of its construction were indicated, while certain theoretical considerations were reserved for the present article.

If we wish to attain the best results in a dynamo electric disc machine we must recall some of the general laws of magneto electric induction.

Firstly. The electromotive force induced in a coil passing through a magnetic field is proportional to the area of the coil, but independent of its shape. The most advantageous coil is one that embraces the greatest area with the least length of wire.

Secondly. If the magnetic field is not a uniform one, or if it changes its polarity at regular intervals, the strongest induced electromotive force is obtained by a coil which is capable of embracing simultaneously the least and most dense part of the field, or in the second case the densest + and − parts of the field.

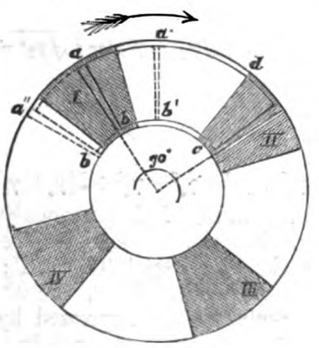

FIG. A.

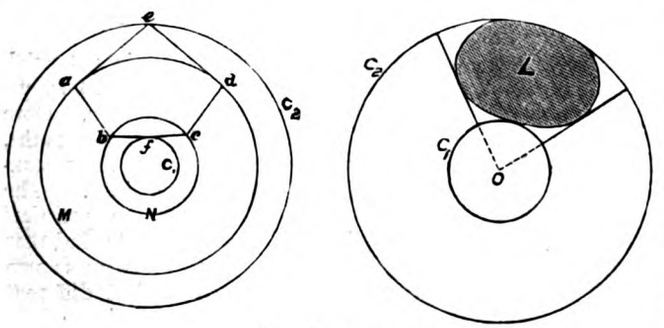
Let us take into consideration a disc machine having four magnetic fields of alternating polarity. Suppose in Fig. A I., II., III., IV. to be the four pole-pieces situated on one side of the armature, I. and III. having positive, and II. and IV. negative polarity. According to the second law referred to above, the ideal form of the armature coil producing the strongest induced electromotive force would be *a*, *b*, *c*, *d*—that is—a "quadrant sector" of the armature, for it embraces simultaneously two adjacent parts of positive and negative densest polarity. The reason is obvious. We must remember that an increase of negative lines of force is equal to a decrease of positive lines, and *vice versâ*.

Therefore, if we make the coil smaller than *a*, *b*, *c*, *d*, say *a'*, *b'*, *c*, *d*, we lose the decrease of negative lines in *a*, *b*, *a'*, *b'*, and if we make the coil larger than *a*, *b*, *c*, *d*, say *a''*, *b''*, *c*, *d*, then between *a*, *b*, *a''*, *b''* an increase of negative lines takes place, and that will balance, or rather annul, an equal increase of positive lines of force at *c*, *d*; thus both are lost as far as induction is concerned.



FIGS. B AND C.

Now, the construction of such an ideal coil is very difficult, for we have to place a great number of such coils close together, the material of which will not allow us to make direct connections between *a* and *d* (Fig. B), and between *b* and *c* along the circles M and N. From the figure it is evident that *a*, *d*, *c*, F, *b* is a quadrant sector, but we are forced to surpass the two circles M and N, the circle M in the outward direction, in order to make some suitable connection *a*, *e*, *d*, and the circle N in the inward direction for a connection on *b*, F, *c*.

Then, again, it is desirable that these new parts *a*, *e*, *d*, and *b*, F, *c*, shall also participate in the induction—that is to say, the pole-pieces should be enlarged in the direction of *e*, F. Thus we obtain two new circles c_1 and c_2, between which the whole active part of the armature is enclosed.

Now, when we sum up all that has been said, we arrive at the following problem :—

(1) Given two concentric circles c_1 and c_2 (Fig. C), to fill up the space between such two circles with coils L of such a shape and size that the surface or area of L shall be as great as possible.

(2) That the tangents of L passing through the centre O shall make a sector as great as possible, but shall not surpass a quadrant.

Thirdly. That there shall be as little space as possible wasted between two adjacent coils and no false inductions. Jehl and

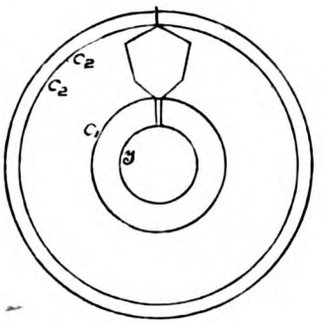


FIG 1.

Rupp have solved the problem in the following manner. As before stated, we have two circles, C' and C'' (Fig. 1), between which the active part of the armature is enclosed. The circle C_1 they call the *inner armature circle*, and C_2 the *outer armature circle*. They now take a third circle, T, smaller than C_1, described around the ends of the coils, which part serves to make connection with the commutator, and also to secure it to the shaft, as has been already explained. This circle T is very important in the construction of the coils, and it has been called the *initial armature circle*, or *the circle of reference*.

If we denote by *n* the number of coils in the armature *d*, the thickness of one coil, and δ the thickness of the insulation between two adjacent coils, the diameter of T is

$$Dy = \frac{n(d+\delta)}{\pi}.$$

That is to say, the circle T is given if the number of coils, the thickness of one coil, and the thickness of the insulation are known. Let us consider first of all such coils as consist only of straight parts (Fig. 2). Suppose *i*, *a*, *f*, *c*, *d*, *g*, and *h* to be one part or side of a coil, while *i'*, *a'*, *f'*, *c'*, *d'*, *g'*, *h'* the side of the adjacent coil as shown. To obtain good results—that is, a large area—we must attempt to make the angles between the lines *a*, *f*, and *d*, *h*, and the circles C_1 and C_2, respectively, as small as possible.

It is obvious that the angle *f'*, *a'*, C_1 cannot be made small at will, but that it is limited by the rounded part *a b* of the preceding coil. In the best case we can construct the angle *f'*, *a'*, C_1 as follows :—

Around the centre *a* we describe a circle, the radius of which is equal to the thickness of one coil plus the thickness of the insulation. The tangent of that circle passing through *a'* is then the line *a'*, *f'*.

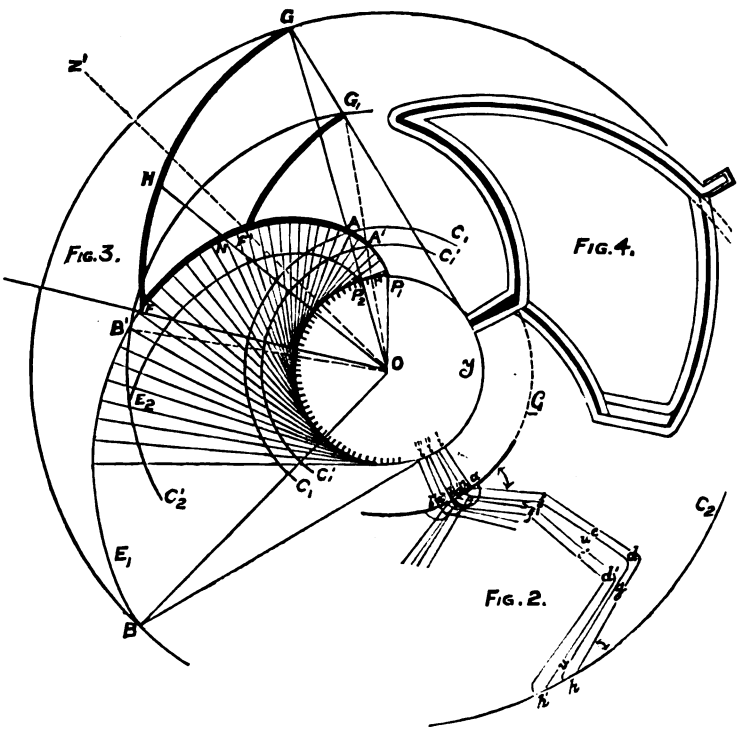
A similar difficulty arises in the construction of the parts *d*, *h*, and *d'*, *h'*; it will be seen that there is a part, *g*, which comes very near the part, *d'*—so near that it is only separated from it by the insulation.

Therefore, in using coils constructed of straight lines we do

Digitized by Google

not arrive at the maximum surface, as there always remains much waste space between the coils, as *s*, *u*, *v*.

Suppose, now, that the parts *a'*, *f'*, are bent so that *f'* approaches *f*, and making also the part *d'*, *h'*, a little longer, so that *d'* may approach *d*. By this means the space *s*, *u*, *v*, is now rendered active. In like manner we can bend the preceding coil *a*, *f*, *d*, and then the coil *a'*, *f'*, *d'* can again be bent further. Hence the question arises, what kind of curve ought *a*, *f*, be? This question may be solved geometrically. Theoretically expressed, a curve was needed, which, when turned around the centre of O of C_1 would in another position remain equi-distant in all parts with its first position. Now, such curves exist, and are known as the evolute of a circle. Imagine a thread wound around the circle T (Fig. 3), and P_1 and P_2 to be two arbitrary but fixed points of that thread. If we wind off the thread, the two points P_1 and P_2 will generate two evolutes E_1 and E_2 of the circle T; that is, two curved lines, which will have at all parts the same distance, and which distance is equal to the arc $P_1 P_2$ of T. The one curve may be considered as obtained by turning the other around O. The circle T is called the circle of reference of the evolutes. As the drawing shows, such evolutes can easily be composed of a greater number of small arcs of circles, the centres of which lie on T.



Suppose C_1 and C_2 to be the inner and outer armature circle, and T provisionally a circle smaller than C_1. Construct one evolute E_1 of T, which will meet C_1 and C_2 at A and B respectively. Trace the radius O A G and O B, divide the angle A O B into two equal parts by the radius O Z. The latter will intersect the curve at a point F. Finally revert the part B F so that it shall form the curve F G, then A F G is the required form of a coil or coils. We have chosen a preliminary circle T smaller than C_1 for the construction of the evolute, but it is evident that we must take T in such a manner that the surface A F G will be maximum. That is the case if we make the angles which the curves G F and A F form with the circles C_2 and C_1 as small as possible. Now the construction shows that the line perpendicular to the curve at G or at B is a tangent of T. Therefore the angle at G becomes smaller, the smaller we make the circle T. The same is the case with the angle at A.

Now we can use the complete curve as the shape of the coils, or, in accordance with previously stated facts, taking notice that F O G is larger than 45°, we cut off the cusp F in order to obtain a coil occupying a sector a little less than 90°, like the right hand figure in Fig. 2. It will also be seen that the space enclosed by F N H is small in comparison with the length of wire, therefore we get better results by cutting the cusp off. It will also be noticed that if the coils are made and formed with the cusp, as shown in Fig. 2, every particle of space between C_1 and C_2 is utilised and is active. However, as before stated, it is better to construct the evolvents so that when the cusp is cut off the complete coil occupies a little less than 90°. In this way we gain more surface in proportion to the length. Of course it is understood that A N H G represents one half of a coil, while the other half has the same shape, only reverted. MM. Jehl and Rupp use two known formulæ, by which a chosen part of the area, such, for example, A N H G and its length, can be calculated.

Supposing A N H G to be one half of a coil, and

$$A O = \gamma_1$$
$$G O = \gamma_2$$
$$H O = \gamma_3$$
$$N o = \gamma_4$$
$$P_1 O = \gamma$$

Then the surface of the complete coil is—

$$S = \frac{1}{3\gamma}\left[{}^{2}\sqrt{(\gamma_1^2 - \gamma^2)^3} + {}^{2}\sqrt{\gamma_2^2 - \gamma^2)^3} - {}^{2}\sqrt{\gamma_3^2 - \gamma^2)^3} - \sqrt{(\gamma_4^2 - \gamma^2)^3}\right]$$

And its length—

$$L = \gamma_4^2 + \gamma_2^2 - \gamma_3^2 - \gamma_1^2 + 2(\gamma_3 - \gamma_4).$$

There is another thing of importance to be noticed. It has been shown that the surface of a coil will increase the smaller we make the initial circle T; but this also diminishes the number of coils. Now, the whole active parts or surfaces of the armature are expressed by S *n*, where *n* equals the number of coils. Now, we can imagine that if the circle T, and with it the number of coils diminishes, the *total surface* may increase considerably. This is the case, but *there is a limit.* If we surpass it, the *total surface* begins to diminish. The following rule may be laid down :—*The radius of the initial circle should be one-fourth of the radius of the outer armature circle.*

One must be careful not to confound the initial circle T with the inner armature circle C_1.

With these principles and facts the machine shown in Figs. 15 and 16 (*Electrician*, June 10) was constructed.

LITERATURE.

Elementary Lessons in Electricity and Magnetism. By SILVANUS P. THOMPSON, D.Sc., B.A., F.R.A.S. [Revised Edition.]

The fact that the publication of this useful text-book has already reached 28,000 copies is sufficient proof of its well-deserved popularity.

Having always a vigorous grasp of his subject, Prof. Thompson also possesses the valuable faculty of clear exposition, a quality which is well displayed in the revised chapter of the present edition on electro-magnetics.

This section opens with the theory of magnetic potential, which is concisely stated and explained. Article 313 is, we think, of especial value to students of the present time. Here the author, stepping aside from the formal scholastic paths, gives in exact and yet familiar language the links connecting magnetic susceptibility and permeability. The latter idea is certainly the one with which the practical student is most at home, and he will be comforted to find that unit magnetic poles, free magnetic matter, and finally his own beloved lines of force and magnetic density are but different aspects of one and the same physical condition, and are held together by no very complex bonds. The conception of magnetic shells as a means of calculating the magnetic effects of closed voltaic circuits, is next introduced, after which follow notes on magnetic and electro-magnetic units, and on the calculation of the earth's magnetic force in terms therein. A somewhat startling computation of the probable number of atoms in the

Digitized by Google

universe, within a radius described from the earth as far as the nearest fixed star, concludes this lesson.

In turning to the succeeding lesson on electro-magnets, the most important article is No. 330, which deals with the relation between magnetic induction and magnetising force. Here we confess to a slight disappointment, for, amidst the mass of empirical formulæ which is considered as "deserving of mention," no statement is made as to that recently brought forward by Kapp, save the remark that it is analogous to Hopkinson's.

Kapp's formula for connecting the magnetic induction with the magnetising force or exciting power is perhaps the most nearly coincident with actual fact which has yet been devised, and it has, moreover, the advantage of great simplicity. As a matter of fact, Hopkinson's formula, as given, is valueless without the aid of experiment or empiricism in finding the values of μ at the various stages of excitation, and whilst it is true that the fundamental idea of "magnetomotive force" acting on magnetic resistance, underlies both formulæ, Kapp's is completed by an empirical law of saturation which gives it a practical value not, as we think, to have been so lightly passed over.

The remaining two lessons of the chapter are devoted to the treatment of electro-dynamics and diamagnetism. We are in full accord with Prof. Thompson as to the incorrectness of speaking of the attraction or repulsion of *currents* instead of the conductors conveying them, since otherwise we must necessarily conceive of a state of strain between the current and the conductor, which would presumably result in an unequal distribution of the former within the latter. The phraseology throughout is at once clear to the student and accurate in itself, and we wish the book a renewed success.

ELECTRIC RAILWAY BRAKE TESTS.

The following is the report of a sub-committee of the American Master Car Builders' Association on the application of electricity to railway brakes. The report is signed by Mr. A. H. Bowman, electrician, Lehigh Valley Railroad; Mr. E. M. Herr, acting superintendent of telegraph, Chicago, Burlington, and Quincy Railroad; and Mr. O. E. Stewart, superintendent of the East Iowa Division of the Chicago, Burlington, and Quincy Railroad:—

In pursuance with the committee's instructions in letter of May 19th we have made an investigation of the electrical appliances used by the Eames, Carpenter, Westinghouse, and Card Brake Companies in the 1887 brake test, and respectfully submit the following report:—As to the use made of electricity, we find the brakes represented naturally divide themselves into two classes, one in which electricity is entirely depended upon for the proper operation of the braking mechanism, the other in which it is used as an auxiliary or addition to braking device complete in itself. In the first class are found the Carpenter electro air-brake and the Card electric brake. In the second the Westinghouse automatic air brake and the Eames automatic vacuum brake. All the above are arranged on the open circuit system, with the exception of the Card, in which the circuit is closed, but the two batteries, one on the engine and one in the rear car, are so opposed to each other that in the normal condition no current passes through the train. In the open circuit system it is to be understood that unless the brakes are either being applied or released, no current is passing or being supplied by the batteries or other electro generating devices. This is also practically true in the closed circuit system employed by the Card Brake Company.

Taking up in order the four brakes examined, we have, first, the Carpenter electro air brake. The electrical appliances used by this brake company consists of a secondary "Julien" battery of eight cells, carried in a box upon the left hand side of the engine, securely fastened to the frame and guide yoke, and two systems of electro-magnets connected in multiple are upon the three-wire systems, one set of magnets operating the admission, the other the release valves. They also exhibited a magneto machine, by means of which the brakes could be operated by the engineer independently of the battery. This machine was not properly adjusted for the work to be done on these tests, and was therefore not used. The following diagram roughly illustrates the manner in which the electric apparatus mentioned above is connected in this brake system.

In this diagram B represents the battery, H the handle of the engineer's valve which closes the circuit A X by being moved into contact with point A, or B Z by being moved in contact with point B. In the first case the current would be caused to flow through the magnets M M1 M11, &c., returning by the common return wire, C Y, operating the admission valves and supplying the brake. In the second case the flow would be through magnets, M M_2 M_3, &c., returning over the same wire, C Y, and operating in like manner the release valves. The connections between the different cars are made automatically in coupling the brake hose by means of contact pieces in the hose coupling. These pieces are held in firm contact by a powerful spring, and are well rubbed, in coupling, making a clean, firm contact. The wires are run under the bottom of the cars and through the hose to the couplings.

The resistance of each electro-magnet was found to be 200 ohms, making for a 50-car train, when connected as shown, a total resistance of four ohms. It is worthy of note that with a battery of constant electric motive force, the resistance being increased inversely as the number of cars in the train, a constant current strength is maintained through each magnet regardless of the number of cars, making no adjustment necessary for different lengths of trains. With this arrangement of battery and resistance considerable current is used while the circuit is closed, but as this only takes place while the pressure is either being increased or decreased in the brake cylinder, it amounts to but a small consumption of battery even for a number of stops. Calculations show that with a 50 car train the breaking force could be increased or decreased continuously for about 17 hours before the strength of the battery would be destroyed, and a proportionately longer period for a shorter train. From the way in which the circuit is run it is easily seen that should an accident happen to any of the wires, causing their rupture at any point, the brakes between such point and the engine would be unaffected thereby, while those on the other section would, of course, be inoperative. This feature would enable the brakes on the forward section to be released by the engineer in case of an accidental break in two.

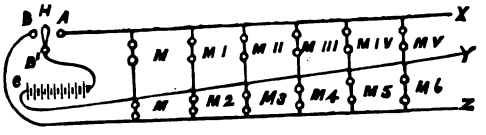


FIG. 1.—The Carpenter Brake.

We come next to the Westinghouse Electric Application Valve.

We found the conducting wires used fairly well insulated throughout their length, except at points where connection was made between wires to valves and the main conductors. No attempt at insulating of these joints is made. Perfect insulation is of great importance in this system, for should a cross occur between the two conductors, instead of the brakes being applied when an attempt was made to do so, the release, as well as the admission valves, would be open, and, should the current be maintained, the auxiliary reservoir train pipe and main reservoir would all be completely bled. Should either wire come in contact with any metallic connection either with the train pipe or any of the braking apparatus, or any part of the car forming metallic connection with the track, the result would be that either the admission valves would cease to operate by electricity, and the brakes could not be set thereby, or being set they could not be released, depending upon which wire was touched or grounded. Rain, sleet, or snow would work very much to the disadvantage of the electric appliances of this brake if the conducting wires are not well or completely insulated. It is perhaps fair to say that this brake can be applied by allowing air to escape from the engine's valve in case the current fails, but cannot be released except by electricity.

In regard to the details, we found the electric appliances admirably designed and well worked out, giving, in our opinion, under ordinary circumstances, a good and reliable arrangement. The magnet and armatures are enclosed in the cast iron cap on top of the valve, but are not within the compressed air chamber. They are separated from the rest of the valve by a heavy brass plate serving to protect the armatures from the magnetic influence of the other iron parts of the valve.

The amount of current used on a 50-car train is about 3 amperes, with an electric motive force of 16 volts, the resistance of the circuit being about 5½ or 6 ohms. Fusible safety plugs are inserted in the circuit next to the battery to prevent the possibility of the magnets being burned.

The next in order is the Card Electric Brake. This company uses two secondary batteries of a form devised by the inventor, Mr. Card, consisting of 15 cells each. One situated under the engineer's seat in the engine, the other on the rear car of the train, so connected as to oppose each other in such a way that no current passes under normal conditions. Also a system of three electric magnets for each brake connected in multiple series, together with an automatic rheostat current indicator and arrangement for cutting in and out as many cells as is desired to give the required braking force, all as shown in the following diagram:—

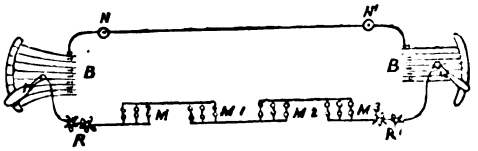

FIG. 2.—The Card Brake.

B and B' are the batteries, M M_1, &c., the systems of electro-magnet, one for each brake, connected as shown, R and R' the automatic rheostats arranged in such a way that should the train part at any point the couplings for the wires are so arranged as to close the circuit on each section, thus cutting off part of the resistance before in circuits an equal resist-

Digitized by Google

ance would be automatically inserted at the rheostat. This maintains he current at a constant strength no matter how many or how few cars are broken off. The brake is applied while running, either by the conductor or engineer moving the handle H or H' and thus cutting in or out some of the cells, destroying the balance, and causing the current to flow through the magnets M M', &c., the amount of flow and consequent severity of application of the brakes being regulated by the number of section over which the handle H H' is moved.

he resistance of each magnet is low, being one ohm, making in resistance of the three used in each car ⅓ ohm when connected as shown. The total resistance of each car, including conducting wires, is ½ ohm, or a total of 25 ohms for a 50-car train. Although considerable current is required for the full application of the brakes, only part of it is necessary for a partial application. The current is passing in this system while the brakes are in operation, for, not only must the current pass to apply the brakes, but it must be maintained to keep them on. Calculation shows that with a battery used of the capacity of 10 ampere hours, 10 hours of the maximum application of the brake could be obtained before the battery is exhausted and of course a proportionately longer period for gentler applications. The conducting wires used by this brake company are not insulated, excepting where they are fastened to the body of the car and consist of galvanised wire cables ⅛in. thick. The couplings are arranged to complete the circuit through one wire by a sliding contact piece in the centre, the return current passing through the outside casings of the couplings. They are designed to pull apart at the couplings under all circumstances, for should the hose and connection wires be ruptured the brakes on neither section could be applied. The effect of a cross between the conducting wires here would be to apply the brakes throughout the train, and as no effort has been made to insulate the conducting wires this is an accident which, in our opinion, is extremely likely to happen either from the direct contact, or by rain, snow, sleet or other causes. The automatic rheostat is also a delicate piece of mechanism liable to get out of order, with the possible result of burning out some of the magnets, rendering the brake inoperative. The principle on which this brake is got up is admirable, but the mechanism employed somewhat complicated for train services.

In the second division we have the Westinghouse Automatic Air-brake. The electric device used by this company consists essentially of a valve inserted in the train pipe, operated by means of compressed air, which raises a piston nominally in equilibrium when its balance is destroyed by blowing off a chamber above it by means of a small valve raised from its seat by the armature of an electro-magnet. The current is passed through a copper wire insulated with rubber insulation and run through the train pipe, the return being through the metal pipe itself. The wire is connected automatically in coupling the air hose by means of contact pieces in the centre of the coupling, giving a firm contact with slight rubbing between the surfaces. The magnets used are wound to a resistance of 11 ohms each, and but three being used in these tests connected in multiple; the total resistance, about 3½ ohms for the magnets, and about two ohms for the conducting wire, is 5½ ohms. The battery used would suffice for a long time, as the wires are so connected to the engineer's valve that no electricity would be used except for emergency stops. The wires are carefully insulated, and, being enclosed in the train pipes, are well protected from the weather. Should a metallic contact occur between the wire and the pipe, however, the result would simply be to render inoperative the electric valves, which, as before stated, are entirely auxiliary to the brake mechanism. The electric features of this brake are well worked out, and, in our opinion, give a reliable and practical apparatus.

The electric appliances to the Eames Automatic Vacuum Brake are also auxiliary to the vacuum mechanism itself. It consists essentially of an electric magnet enclosed in a cast-iron cap or chamber, which can be put in communication either with the vacuum or the main valve auxiliary reservoir or with the atmosphere according as the circuit is made or broken, as explained on page 24 of the Eames catalogue. Also a metallic circuit composed of a single conducting wire and the magnets connected, as shown in red on the cut submitted herewith, the return being through the rails of the track. The current is supplied by dynamo having an armature 9in. long and 8in. in diameter; this dynamo has no governor, and is entirely beyond control and varies greatly in speed. The magnets, as is seen, are connected in series, making the total resistance equal to the sum of the resistances of the conducting wire and all the magnets, necessitating a very low resistance, in the latter 12 ohms each, and a current of considerable strength to overcome the entire resistance, which is for a 50-car train about 30 ohms. The conducting wire is fairly well insulated, and being run through the train pipe is well protected, except where it is connected to the spiral wire through the hose. The effect of any metallic contact and the conducting wire and the parts of the car in metallic connection with the track would be, as far as the electrical attachments are concerned, to cut out all the brakes between this point of such contact and the rear of the train. If the conducting wire be broken or detached in any way causing a break in the circuit, the entire electric apparatus fails. No effort was made to protect the armatures from the effect of the close proximity of iron in the other parts of the valve, and in several ways the details of the electrical attachments might be improved. The use of the track as a return is to be deprecated on account of interruption to current in case of insulated track sections put in block signal systems, drawbridges, &c.

It seems to us the whole question of the application of electricity to railroad breaking resolves itself into three important questions. First, can a valve mechanism be made operative by electricity which shall be permanent and practicable for railroad service, not having parts too sensitive or of too fine adjustment? We think it can. The valve construction as shown by Mr. Carpenter, the same which he used in these trials, is certainly not more delicate and complicated than that of the well-known Westinghouse triple valve. Secondly, can the electric conductors for working these valves be so insulated and projected as to avoid short-circuits and other injuries? We think it can by running the wires inside of the air pipes, where they are as little liable to derangement and injury, and become as permanent and certain in their functions as any other feature of the brake mechanism. In all the electric brakes shown the wires are laid inside the air hose coupling, where they are fully protected, and their connections are made from car to car easily and certainly, so that this important point is so far settled as to require no further explanation.

The remaining point is the source of the electromotive force. Of the different means employed by the companies represented, the secondary battery appears the most reliable, giving a constant current all the time until discharged, recharging being a simple process, which can be so methodically and practically arranged as not to interfere with the brake service, nor add materially to the expense. If brakes worked by electricity are to come into general use, it is probable that both battery and dynamo will give way to the magneto generator, being a small machine about 18in. square, having an easily turned crank which instantly develops the electromotive force required, so that a turn of the crank will actually apply or release the brake. One of these machines was shown us in operation upon an engine and tender brake. This apparatus may solve a most important point connected with the application of electricity to railroad brakes, inasmuch as it renders the apparatus on the locomotive independent of any special station or roundhouses, or any stated period when a battery, if used, would have to be recharged.

We believe from what we have seen at the Burlington brake tests and from a close personal examination of the several electrical arrangements for braking, that electricity properly devised and managed may be made a valuable auxiliary to actuate power brakes on long trains, and their efficiency considerably increased thereby.

CORRESPONDENCE.

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Since my letter of May 27th there have been several in your journal on the subject of electric light tenders, but very little, it seems to me, was said that is to the point. Take, for instance, the letter of Messrs. Anderson and Munro, of June 3rd. The greater part of their letter has little to do with the subject under consideration, and personally I agree with Mr. Carswell in ridiculing their estimate of £4 per carriage for fitting up the same with from eight to ten lamps. If Messrs Anderson and Munro, by their correspondence, intended to pose as the champions of good work at a remunerative rate, it is unfortunate that they committed themselves to figures. In that part of their letter, however, which does affect the question, they suggest that architects know at once, by a rule of thumb method, what gas jets are required in a building, but have very vague ideas as to the number of electric glow lamps required for the same building. But if an architect is of opinion that fifty gas jets, each of 15 candle-power, are required in a certain sized building, then surely he must also be of opinion that fifty glow lamps, each of 15 candle-power, would be required in the same building; otherwise we are forced to conclude that an architect does not know the amount of light a certain sized burner will give.

Undoubtedly the views set forth by Mr. W. C. Mountain are sound. Why do we not have in every case a regular specification, as has always been the case in engineering? Why is electric lighting to be exempt from the custom and practice of other classes of engineering?

I quite agree with Mr. Mountain that the one and only way out of the difficulty is to place all work in the hands of a consulting engineer. Mr. Sydney F. Walker, in his somewhat verbose communication, draws a parallel between electric engineering and the "red herring and potato" line, which, I think, we may at once dismiss from the discussion if we are to admit that the former has any place among the sciences of the world; neither do I think it fair to suggest that consulting engineers are as a body corrupt or corruptible. In any case, what has proved beneficial in the case of engineering generally ought not be abandoned in the case of electrical engineering. What applies to one equally applies to the other.

There can be no doubt that the "cheap work gentlemen" not only thrive but bring great discredit upon electric enterprise generally, and if the consulting engineer would be the means of getting rid of them, by all means let us have him.

I will give one instance where the contractor managed to get rid of the consulting engineer.

Digitized by Google

A party of gentlemen wishing to start a Central Station in their town called in the services of a consulting engineer, who, after carefully going into the whole matter, advised them that it was impossible to charge less than £2 per lamp per annum for glow lamps.

The representative of a well-known touting firm came by, and assured these gentlemen that they would make a handsome profit if 25s. were charged. *The services of the consulting engineer were no longer required.*

I myself, quite recently, was censured for recommending that a depreciation of at least 10 per cent. should be allowed for on the cost of a large installation of engines, boilers and dynamos, when estimating the annual expenses, and was told that nothing ought to be allowed the first year, and about 2½ the second. Here, then, is one chance for wide variations in estimates. Yet another.

Many consider that 50 watts for a 20 candle-power lamp is an outside allowance, and hold it as an axiom that engines of all sizes can be safely loaded to three times their nominal power.

Example: A 4 horse-power nominal engine will indicate 12 horse-power, and, reckoning 10 lamps to the horse-power, will carry 120 lamps! Is there not room, Sir, here for variations in tenders?

The suggestion that a definite standard of illumination for a given space should be adopted by engineers is absurd on the face of it. Does a back kitchen require to be as well lighted as a nobleman's dining room, or, in the case of arc lamps, does a space 100 yards by 100 yards require the same number of lamps as a space 10 yards by 1,000 yards?

We have had enough of vague and meaningless units, pray do not let us add to their number.—Yours, &c.,

J. N. V. MONEY-KENT.

Connaught Mansions, Victoria-street, Westminster, S.W.,
July 20th, 1887.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There seems to be more mystery about the relation of a magnet to its field than I anticipated.

I gather from the letter of Mr. Scattergood that a cylindrical magnet rotated on its axis does not excite a current in a stationary conductor situate in its field, while the conductor itself, if rotated in the same way relatively to the magnet, does give a current. This, too, seems to be the view of Mr. Voice, who endeavours to show that a current is produced in the magnet itself when rotated about its magnetic axis, so that although rotated in its own field it is affected just as if its magnetism did not belong to it. According to these views, therefore, we may consider magnetism to be possessed of *infinite* inertia with regard to rotation about the magnetic axis, at least in all cases in which the field is symmetrical about the axis, as in Forbes's dynamo, and, I suppose, in magnets of different section also. Applying this theory to the case of the Forbes dynamo (I have adopted Mr. Thompson's suggestion), we have a sort of reason for the current generated in its armature, notwithstanding that each point of the armature is throughout its revolution in a field of the same intensity and direction. It also gives us reason to expect that if the armature be fixed and the rest of the machine revolved around it, we shall have no E.M.F. in the armature, but shall have it in the field-magnet, &c., instead.

I am unable to accept this view, for the following reasons:—A current circulating in a coil of many convolutions induces that state of polarisation in surrounding matter which is designated magnetism. We may consider the molecules of this surrounding matter so affected to be polarised in closed chains, enveloping the coil, by a constraining force acting outwards from the coil.

These closed chains of polarised molecules are represented in value and position—of course, not in number—by the conventional "lines of force." When the armature of Forbes's dynamo is rotated the continuity of these chains is broken, and fresh chains of molecules become forthwith polarised, so as to preserve the same aggregate value. The continual rearrangement of the molecules of the conductor involves the production of an E.M.F., and if there be not a path open for a current nothing more, the polarised molecules simply turning over, so to speak, their polarity to fresh sets of molecules, so as to restore the continuity of the chains in their former positions continuously, so that no resistance opposes the motion of the conductor. But if there be an outlet for current the E.M.F. is lowered and the energy is only partly "turned over" as above, so that induction must, in that case, restore the chains, and a mechanical force must be exerted in order to sunder them, the energy thus absorbed appearing as current.

Whether the last sentence or two be correct or not, what does it matter? For whether we rotate the armature or the field-magnet, if there be in each a path open for Foucault or other current, the molecular chains must be sundered by a mechanical force, and why must the whole transformation of the energy take place in either the one or the other alone? I certainly see no reason, unless it is that the *position* of each chain is fixed relatively to that element of the exciting coil from which it springs. But in that case rotation of the coil alone about the magnetic axis would entail rotation of the lines.

I have a strong presentiment that it will be found that what prevents the positions of the lines of force from rotating along with the armature is the powerful retardation due to the generation of Foucault currents by the positions aforesaid cutting through the iron of the field-magnet, &c., their speed of revolution being that at which their motion through the iron of the field-magnet supplies a reaction equal to the pressure of the armature against them, the ratio of energy utilised to that wasted being as the velocity of the positions (lines) through the armature is to their velocity through the magnet.

The problem may be thus definitely stated. May we regard magnetism as possessing infinite inertia with regard to rotation about its axis, according to the views of Mr. Scattergood and Mr. Voice, or is it *quasi* fixed to the exciting coil, so as to be bound to accompany it when rotated (which I take to be Mr. Thompson's view), or is the view expressed in my original letter (*The Electrician*, July 1st), and now repeated, the correct one?—Yours, &c., R. SNOWDON.

Staveley Ironworks, July 20th, 1887.

[CORRESPONDENCE *continued on page 227.*]

THE LIGHTNING RECORD IN GERMANY.—From a recent report by Dr. Hellman on statistics of lightning-damage in Schleswig-Holstein, Baden, and Hesse, it appears that the danger from lightning in these localities (unlike the case of other parts of Germany) has been decreasing of late years. Soft-roofed houses are fired about 7 times oftener than those with hard roofs. Windmills are struck 52 times, and church and clock towers 39 times, oftener than ordinary houses with hard roofs. The marshy regions in Schleswig-Holstein are the most dangerous, and the land about inlets of the east coast the safest. With like conditions, the relative danger decreases the more houses are grouped together. In Baden the danger varies more than in any part of Germany (about Heidelberg it is 24, and in Waldshut 265 per million houses). In Hesse the low plain of the middle Rhine is the most dangerous part. In the fifteen years 1869-83, there were killed by lightning for every million men in Prussia, 4·4; in Baden, 3·8; in France, 3·1; and in Sweden, 3·0. The geological nature of the ground, and especially its capacity for water, has important influence. Thus, calling the danger on lime 1, that for sand is 9, while for loam it is 22. This is partly why most of South Germany and Austria is less dangerous than North Germany. There are four factors affecting the lightning danger to buildings; two physical—unequal frequency of storms, and geological character; and two social—variable population, and mode of building. Of all trees, oaks are most frequently damaged, beeches most rarely (in the ratio 54 to 1).

THE LIGHTING OF THEATRES.

Following up the appalling disaster at the Paris Opera Comique, the *Saturday Review*, with a public spirit which we highly commend, has instituted an inquiry of its own into the condition of the theatres of this metropolis, the results of which are being made known from week to week in the pages of that journal. The thoroughness and fairness of this remarkable series of articles can hardly fail to be the means of effecting many greatly needed improvements in our places of public entertainment. But the inquiry has naturally been directed chiefly to the means of exit in cases of fire, and has done little or nothing towards preventing the prime cause of the outbreak. Of the electric light, the *Saturday Review* Commissioner says hardly anything, except to notify where it is in use; and he is positive only when recommending the employment of oil lamps as an additional security against panic when the gas is extinguished. We shall venture to offer a few observations on these two points presently. But let us see first of all what is the actual state of affairs which this journalistic inquiry has brought to light.

It is no exaggeration to say that not one theatre in a dozen is provided structurally with places of egress adequate to the requirements of a large and widely scattered audience, and recent attempts at improving these shortcomings have generally resulted only in providing doors which are commonly locked, or passages which look like outlets but lead to nowhere. Some theatres which make the greatest parade of their "exits in case of fire" appear to have expended just the price of the labels and no more. If, indeed, the passages over the doors of which these cheerful notices are affixed have any specific object, it would seem to be to accumulate the audience finally all at one point, and jam them there till they are trampled or crushed to death, should they have escaped the suffocation which would certainly overtake those who are stuck fast in the passages behind. Most of these structures have for the great bulk of the audience but one main outlet, to which all or nearly all the other "exits" converge; and in some cases this outlet is frightfully distant from the building, to which it is connected by tortuous windings or dangerous staircases. To these structural hindrances to rapid egress the management usually adds some strong barriers to prevent ugly rushes before the play begins, and which, being kept up all the time the play is on, would assuredly lead to calamity if a frightened audience wanted to get out.

Now, bad as all this is, we are bound to say, after carefully looking at the evidence, that, with the exception of a few obvious reforms, such as the abolition of the vestibules in all theatres, and the absolute closing of some, there is little that can be done structurally to materially remedy the evils complained of. More correctly, we should say, too much would have to be done; for we know from what the *Evening News* says of its interview with the Chairman of the Metropolitan Board of Works that legal action can be taken only when "structural defects can be remedied at a moderate expenditure." Our ideas of safety when most of these theatres were built were different from what they are now; and it would do violence to public opinion were a building condemned, and its owner ruined, because we had neglected our duty in the first instance. Some valuable improvements can still be made, no doubt, at a "moderate expenditure;" and we sincerely hope that the revelations which we owe to the *Saturday Review* will be the means of getting everything done that can be done to mitigate the horrors of a catastrophe from which not even the best constructed theatres can be rendered wholly exempt.

But it is one thing to guard against the consequences of panic, and quite another to prevent the occasion of it. Now the cause is almost invariably fire, and except in very rare instances the cause of the fire is gas. The mere smell of escaping gas has led to the turning of it off at the meter, with the usual consequences to the unfortunate audience. Generally, however, the fire originates in the wings, or somewhere behind the footlights, where there are plenty of naked lights and an abundance of inflammable materials. Not only are the gas-lights a permanent danger, but the gas itself is an additional element of terror. Consequently the first thing done in any case, whether the fire originated with the gas or not, is to turn it off. Permanent oil lamps, as used at some of our best managed theatres, if placed at every suitable spot, would go far to allay the fears of an excited crowd. But oil lamps are troublesome, expensive to maintain in large numbers, and by no means a perfectly safe kind of light. To duplicate or split up the supply of gas would not meet the requirements of an emergency such as we have to guard against; no one would know at the critical moment which source of supply was at fault; and, probably for reasons already adverted to, the whole of it would be instantly extinguished for fear of an explosion.

Here, then, we have the indisputable fact that the employment of gas in theatres is not only almost wholly responsible for the outbreak of fires, but is wholly responsible for the disastrous consequences that ensue. Bad as our theatres are they are not so ill provided with exits as to render escape even for a large audience perfectly practicable if there is light enough

Digitized by Google

to guide the men and to pacify the women. But in total darkness even an English crowd could not be trusted to act with fortitude and patience with unseen terrors in front and in rear. It is all very well to multiply outlets, but if the people cannot find them, or cannot see their way when found, the result must be fatal stumblings and a speedy block.

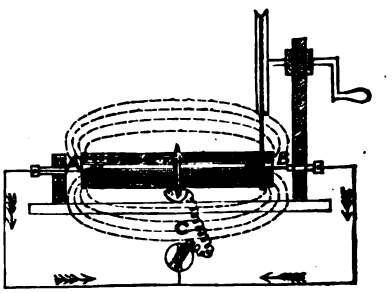
In short, we are led to one broad conclusion, that the best and, indeed, only way to insure the safe exit of both audience and actors in the event of an outbreak of fire is to provide them with a perfectly trustworthy light, which shall neither be itself the cause of fire nor be liable to extinction if a fire break out. We have no knowledge of any mode of lighting, except by electricity, which would fulfil these conditions. We freely admit that even the electric light if carelessly installed might give rise to a serious conflagration; but what we do confidently assert is that it, and it alone, is the light that can be laid on and used with perfect certainty of immunity from this danger, and, moreover, that it can provide the supplementary lights which in all theatres are a proper and desirable safeguard without any risk of extinction whatever. For these safety lamps storage batteries could be charged by the dynamo when not in use for the main system; and no conceivable accident could occur to extinguish both lights at once. An accident to one would be inconvenient, but it would not be fatal; whereas an accident with the gas is almost invariably the beginning of disaster, and is generally the unwitting cause of its horrors being intensified and prolonged.

NON-POLAR OR CORE DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In discussing scientific phenomena, involving as they do natural laws and principles, I think it is undesirable to give special prominence to any particular machine except by way of illustration. For this reason I retain the above title in this correspondence. Whether the word "non-polar" is the best title for this class of dynamos is an open question. I think the second name, as above, would be the best. Mr. Thompson's quotation from Mr. Scattergood's letter would seem to suggest that the latter gentleman is influenced by an out of-date theory. To argue that it is necessary to move a conductor in a varying magnetic field to produce current, or, as the stereotyped phrases go, to add or subtract lines of force, or to increase or diminish the magnetic potential with respect to the movable conductor, by which text books have so long befogged electrical students, is misleading and opposed to facts. It is a positive defect rather than an advantage, but one that cannot be, or has not been, entirely avoided in the construction of dynamos that are required to deliver a comparatively high E.M.F. For that reason this theory has probably been exalted into a "necessity." In a letter to you which appeared on March 8th, 1884, I tried to demonstrate this fact as applied to every known dynamo, both continuous and alternating.

In referring to Weber's experiment, as illustrated in De la Rive's work, and reproduced in a modified form, Fig. 1, in my last letter, Mr. Thompson says:—"When we consider that the collector at the centre (although traversed by a symmetrical field) is under greater inductive influence than that at the end, it is easy to divine the cause of the current." I cannot agree with Mr. Thompson in this. The lines of force, as they go from one pole to the other outside of the magnet, are much more widely distributed and much less concentrated than they are near the poles; and given two conductors of the same area fewer lines would be found to act on the conductor at the middle of the magnet than on that at the pole. However, it is not necessary to have a flange at the pole, as I indicated. Electrical contact may be made at the pivot with like results. For the moment I will accept Mr. Thompson's explanation—which is the same as De la Rive's—in order to analyse it. We will therefore assume the current *is* produced by the rotating magnet and magnetism acting on the conductors unequally. Let the resultant product be represented by 1, while contact is made at the middle and at the pivot A. Under these conditions it will be seen that only one pole or half of the magnet is acted upon. The wire from A may extend any distance in a direction parallel with the axis of the magnet, and will be totally unaffected by the magnetic field, while the other wire will be in the most favourable position to suit Mr. Thompson, and according to his view the current will be produced solely by the lines cutting this one conductor at the equator of the magnet It is understood that the resultant current equals 1. Now, let another conductor be in contact with the other pivot B, and joined to that leading from A, as in the accompanying figure. The speed of the magnet being the same the resultant will now equal 2, just double. Where could this increase of current come from? The number of lines acting on the middle wire in one revolution is the same in both cases, and it is only possible for them to intersect the middle conductor. What will Mr. Thompson say to that? If we regard the magnetism as being stationary while the magnet rotates, and is itself the movable conductor, the double effect is easily understood.



Mr. Thompson goes on to say:—"It is undoubtedly true that in an ordinary dynamo current is produced by the reaction of a condition that itself is instrumental in maintaining." Perhaps I am dull of comprehension, but this passage seems to me to be somewhat vague. I presume he has the self-exciting properties of dynamos in his mind. If so it is a little wide of the question at issue. Do not the armature cores of the Gramme, Siemens, and other continuous current machines revolve at a terrific speed *through* this rigidly fixed though apparently ethereal force? And does not this fact conclusively show that magnetism is separate from and independent of iron? If the lines of force existing between the N. and S. poles of a powerful dynamo are so demonstratively immovable, why should they not be equally immovable in a cylindrical bar magnet? In other words, why should not a cylindrical magnet rotate axially through the magnetism as easily as the Gramme ring revolves longitudinally through it? I say "axially" and "longitudinally" because, in the case of the bar magnet rotating on its axis, the iron molecules move across the polar direction of the magnetism, while in the Gramme ring they move along the polar direction. But it may be said that the magnetism between the two poles of a powerful dynamo emanates from and is held in position by the two field-magnets. Then, does its retention in that position depend on the strength of those magnets? Or, would an excessive power, acting on the magnetism between the two poles, move it from them? In short, is it simply a question of degree as to its fixity or its removal? Existing machines of all sorts and sizes, actuated by varying power, silently bear witness that it is not, but that the magnetism is immovable, although opposed to a force of several horse-power. I will not complicate my argument by alluding to the advanced poles in the revolving Gramme ring.

Mr. Thompson is also of opinion that "the magnet and its field are as intimately connected with each other as the atmosphere and earth of our terrestrial system, and would with as much reason revolve together." I confess I do not quite see the point of this analogy. The atmosphere can be separated into its constituent gases; can be accurately weighed; its pressure calculated and its presence known to us by the

Digitized by Google

sense of touch. But we know very little of magnetism—only as it influences other bodies. It apparently has no weight; still its power is exerted through many of the most dense bodies without sensible retardation and without altering its nature.

This mode of obtaining current from a rotating magnet was discovered about fifty-five years ago by Faraday and Weber. Faraday's experiments are not so mechanical and striking as the above simple experiment, although his experiments were more varied and apparently more abstruse. That such a valuable principle should have lain dormant so long can only be because the somewhat elaborate explanation by a philosopher of De la Rive's standing was erroneous, and for that reason its apparent insignificant action was overlooked by subsequent minds.

As it is I venture to prophesy that if certain mechanical difficulties can be overcome, such as taking off the current and getting sufficient E.M.F., the development of this principle will be likely to give a fresh impetus to electrical industries. If Mr. Thompson continues this discussion, I should be glad if he would just notice the reverse action, viz., the rotation of magnets by currents. Perhaps it may help to bear out his views on the subject.

To conclude. By proving the independence of magnetism from the iron in which it may be concentrated, in such a way that one is at rest or fixed in space, while the other rotates, I believe I am justified, by inference, in applying the same law to our terrestrial system. If I may be allowed "to soar into the realms of speculation"—for it does no harm—I am of opinion that magnetism pervades all space, and that it assumes its polar properties only as it is in proximity to bodies that contain iron, such as the earth. Its directive power, viz., that which causes the compass needle to point in a certain direction, is perhaps caused by the distribution of iron in the earth, which may be such as to form a huge magnet, of which the subject matter of this discussion and the enclosed figure is a miniature.

—Yours, &c., E. L. VOICE.

PACKING BATTERIES FOR SHIPMENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Through the very bad attention to packing batteries for shipment to the Colonies the breakage is something fearful. I have just unpacked a gross of Leclanché cells and find no less than thirty smashed. I think this matter wants attention in general, and I know of no more sure way of obtaining it than writing you.

The way of packing I would suggest, should be to put not more than twelve cells in separate boxes. If information from this quarter would be of use I shall be glad to forward.

Trusting you will give this publicity.—Yours, &c.,

Brisbane, June 3rd, 1887. JAMES TRACKSON

AN ATTEMPT TO UNDERSTAND THE MATERIAL NATURE OF ELECTRICITY.

BY SAMUEL E. PHILLIPS, F.C.S.

In the schools we are taught, as matter of fact and knowledge rather than of hypothesis, that there is a "luminiferous ether," which not only does miraculous work in space, but, condensed in all the molecules of matter, it affords endless amusement to the metaphysician and physicist.

This hypothesis has met with the severest castigation from some of our ablest writers, and certainly cannot be considered true philosophy. Nevertheless, that there is an all-pervading something which has not been laid hold of by our chemists or biologists is patent in many ways, and the following is an attempt to understand somewhat of its character and mode of working.

The world is an assemblage of atoms of differing properties; with a strict uniformity of these we should inevitably have absolute death, the stillness of equilibrium, and the opposite of that endless change which now constitutes the life of the universe.

Atomic diversity necessarily involves two things—tension and motion. Tension is the expression of static equilibrium, polarity, magnetism; motion is the expression of atomic change, electricity, chemical action. One is the tendency, as the other is its fruition. Each of these fundamental affections admits of a two-fold aspect or division; they are either mechanical or chemical. The distinction is not one of absolute and total separation. Nature has no gaps, no rigid lines of demarcation; hence both these aspects in some cases mingle and coalesce, while in others we have a bold and distinctive separation.

Mechanical tension is the expression of abstract static equilibrium, the foundation of all acoustic phenomena, or another word for elasticity.

Polar tension is the expression of special or linear static equilibrium. If to the former state of particles we superadd the fact of varied atomic force, we get the fundamental idea of elective affinity. Thus, if we place a light gas upon a heavy one, the simple law of mechanical tension would involve a continuance of such relative positions; but a new tension, a linear directive force, is instantly exerted. Nor does the motion and interchange of particles cease until the resultant expression of both forces is fairly established.

On this view of the case, the extended inquiry whether atoms have different properties on different sides seems utterly uncalled for, since we thus inevitably come to the required conclusion in all binary compounds; and the probability is great that the material universe is constituted on a binary type, and that all the metals and gases of elementary chemistry are indeed binary. At any rate, there can be no doubt in regard to the two gases in question that linear directive forces are in operation, and calling the light gas H and the heavy one O, the tendency would be for all the O atoms to point downwards, and, conversely, for the H atoms to point upwards. In such case we may imagine a gaseous magnet with N. and S. sides or ends. Of course the terms north and south are purely empirical, and mean nothing beyond oppositeness; but whether they be negative and positive, or *vice versâ*, is one of the things demanding immediate settlement.

Mechanical motion (within atomic limits) is the propagation of force or impulse in elastic media; thus sound consists of the simple vibrations of any elastic medium, and the lines of force radiate in straight lines upon well known principles.

Polar motion is not a mere vibration to and fro, but an actual change and displacement, a chemical transfer, a something transmitted; whereas, in the propagation of force, it is the abstract affection only that is transmitted. In polar motion the atoms are actually transferred to whatever distance, and such is the case with every form of galvanism or current electricity. Of course an atom liberated at London does not fly to New York, but intermediate atoms are moved or affected in such way that a corresponding atom is liberated at New York

Chemical action is a confused assemblage of small circuits of action, and in most cases a kind of double decomposition.

Galvanic action is the same process, with a definite linear arrangement instead of a confusion of small circuits.

In any case of double decomposition we have the true analogue of all chemical or electrical change. Two binary compounds decompose each other, to a better saturation of electro forces. The action is essentially composed of two halves, or, in other words, is that of a circuit. If an atom of acid tends in one direction, then an atom of alkali reciprocally tends to the opposite, and the tension or momemtum of one is the exact measure or complement of the other. While tension lasts the state is a polar or magnetic one. While motion lasts there is chemical electrical action. And this brings me to my chief assumption, viz., that all chemical action is binary, or, in other words, *that metals conduct by electrolysis.*

It is curious to note the character of modern inquiries as to whether liquids may not in some cases conduct without electrolysis, after the manner of metal wires, &c.

The underlying assumption has long appeared to be both hasty and inconsiderate. We have a polar motion going on

Digitized by Google

in two opposite directions, one through the metal, the other through the fluid, and chemical action takes origin at the two terminal junctions. Now, if we, in disregard of all dual principles, attribute the sum of both actions to one half of the physical conditions, then, of course, the other half, being so far degraded, may be considered as a mere passive conductor. But if we would recast our thoughts and take a broader view, it might be well to throw aside the wire complication and suppose the metal area of conduction to be equal to that of the liquid. We thus take one side or half, and for every negative ion O lost or given up by the liquid conductor we have a corresponding positive or metallic ion Zn given up by the metallic conductor or electrolyte, and what takes place at one pole is the perfect antithesis of the other—where the liquid gives up the ion H, and the metal yields the negative or electrical ion E. It is true we have here an element truly hypothetical. Be it so. But then much may be said for the necessity, the force, and simplicity of the assumption.

Whether regarded as an item of force, or of matter, it is very certain that something is wanted before H can be liberated, and equally certain that something does actually pass from the Zn to the H pole. What it is, and the mechanism by which it passes, may be best studied by a generic estimate of the two halves of action upon dual principles.

Cut either side in half and all action is stopped. One is as vital as the other. Starting from the Zn end, O cannot join Zn until its opposite ion is liberated; or, oppositely, Zn cannot combine with O until its opposite ion E is liberated.

But H in travelling to the other pole cannot go through the other particles, and therefore *must* go round them, and hence its spiral course in that direction; and, oppositely, E cannot pass through the atoms of metal, and therefore its spiral course.

It is familiar to every tyro that we have no action without completing the circuit, and that the wire half cannot be completed an instant without the passage of E, evidenced by the weak electrolysis of iodide of potassium or otherwise; but, as in the liquid half, the chain of travelling O's cannot move one tittle without the correlate movement of H in the opposite direction, so we cannot imagine the very weakest electrolysis in the wire half without an equal action in both directions.

The apparent result may depend on the manner in which we estimate the phenomena; for instance, if we insert moistened tanno-gallate paper between points or poles of copper or iron we may then get, as before, certain evidence of the passage of E in the metal half of the circuit. But however common this mode of action in a Bain printing telegraph, yet that it is so far apparently one-sided, and that the metallic half of the function is only concealed, will be evident if we simply invert the terminals in question, the so-called current and all other conditions remaining the same.

Now the passage of E is concealed, and we have apparent *the passage of metal*; the positive iron is actually and visibly transferred. With this change of visible aspect there has been no change of the current phenomena; E passes precisely as before, and we may show it in another part of the circuit. And as in the second case metal passed to a visible ink-making result, so in the first case the action was identical, although the transparent copper may not have been so palpable to observation as the ink-making iron.

It is as curious as it is instructive to rightly understand the action going on in both halves of the circuit. That action is essentially similar in both; both are magnetically neutral in the static condition of rest; both are transversely magnetic during action. But, strange to say—yet we do say it with confidence—*there is no electricity passing through the electrolyte*; the interchange of ME in one half is correlated with a similar interchange of HO in the other; nor is the inductive or magnetic effect in any way due to any individuality of ion. What O does in the circuit may be done with Cl, I, or any electro-negative element; and, conversely, what H does may also be done by a like induction from copper, sodium, or potassium.

Nor does it materially alter things if we entertain the more complex modern notion of + Zn on one side, and the – hypothetical radicle (SO^4) on the other; but in favour of the simpler view we may note that chemists *now* admit that this radical "never has been isolated, nor is it likely that it ever will." And in the modern attempts to measure the *volt* power of a Daniel cell, in terms of the thermal effect of actual combustion, expressed in French calories, it is immaterial whether we calculate the energy of $Zn + O - Cu + O$, or the more roundabout process of $Zn + O + SO^3 - Cu + O + SO^3$. Do we thence infer that sulphuric acid is a non-essential? Far, very far, from it. What we do know is that the oxide of zinc, first formed, would be a non-conducting impediment were it not removed by solution, and the acid otherwise materially augments the conductivity of the badly conducting fluid.

It is an indispensable aid to practical working, but it offers no impediment to the simpler or more abstract view we have taken.

If the prevailing ideas that electricity is a mode of force be correct, then, of course, the views here enunciated are but idle speculations; but let us further and fairly consider the matter.

If the chemical formation of oxide of zinc, or the falling together of ZnO, with its energy of more than 40,000 calories, communicated an atomic shock through the metal half or conductor to the other pole, then it would and must be transmitted in straight lines; and where, then, would be the transverse inductive effects now observed? The hypothesis of mere force is untenable at every point. The idea of communicating force through a wire 1,000 miles long is a wanton absurdity; whereas, if we decompose the binary conditions at one end, it requires no stretch of the imagination to see that this atomic interchange may, nay must, be propagated to any length.

We have seen that force is propagated in straight lines, and when free these are radiant in all directions, so that 10 particles affected at A may excite 100 particles at B with 100th of the potential of those at A. All such forces involve an essentially radiant propagation, while electricity is essentially linear and not radiant. In one case force is propagated; in the other an actual transfer of material particles subsists all along the lines of action. If 10 atoms are affected at A, then only 10 atoms can be affected at B. The lines of force may open out, but in themselves they are not radiant; hence it would be quite possible to electro-plate in New York by means of a battery in London, and for every atom of Zn consumed at one end a corresponding atom of silver or other metal would be deposited at the other.

This leads to the remark that in actual practice we greatly modify the metal half for special purposes by coils, or connecting wires, &c. But in all this there is no departure from the common dual character we have supposed to subsist in two equal halves; only it so happens that copper is an infinitely better conductor of the atomic interchange than water or other fluids.

It is, however, a great mistake to suppose that we can insert wire lengths which conduct otherwise than by electrolysis. In order to see this more plainly let us cut our electrolytic fluid in half and insert a straight tube; we have then the perfect analogue of the wire insertion. There is no visible electrolysis at the points of junction, and it simply conducts like the rest of the fluid; or by inserting a spiral tube the convolutions would increase the inductive effects precisely as in the wire coils used for that purpose. We try our utmost not to diminish the area of fluid on account of the increased resistance; yet we may and do greatly extend the metal part. But in either case the vital fact remains that the entire circuit is strictly limited to and governed by what is taking place at the ends or poles of causation. We know that by polarising a bar of iron, or making it ME ME, elongation takes place, and that by frequent reversals of this polarity the friction of the spirally changing atoms produces heat, as all friction must. And yet, further, that during the moment of interchange a spiral or transverse magnetic induction subsists precisely like that in the battery fluid or wire conductor. But in this case there is no mysterious fluid passing from any battery or electro motor. The ends are free or insulated, and there is only an atomic reversal of position.

Digitized by Google

What is now desiderated is that Prof. Tyndall, or some other physicist of like means and abilities, should repeat these demonstrations with a bar of HO instead of ME.

Let us first see the polar condition of water—in fact, the evidence of a water magnet. Secondly, let us see the evidence of heat generated by a continued reversals of its constituents; and thirdly, let us see evidence of the tranverse magnetic effect of its changing particles—in short, magnetic and electrical effects producible without any electricity whatever.

It is not easy at the outset to arrange a voltaic series or linear case of double decomposition totally excluding E from the circuit; *but it will be done.*

In conclusion, what is magnetism, and what is electricity? *Magnetism* is a binary polarity of atoms; it is a static polar tension, and the influence is communicable by induction through all media. As we have good and bad conductors of light, heat, sound, or electricity, &c., so different media have their special capacities for the conduction of polar force.

A non-recognition of this plain and simple fact has greatly vitiated the modern researches on diamagnetism, and in some sense all the philosophical and mathematical developments are a great mistake; but while these researches have reference to a new force, which to me has no existence, still there has resulted from such great endeavours a vast body of new and valuable facts in illustration of the laws of conduction for polar force, and Faraday's "Researches" will long be appealed to as one of the most valuable text books in a new field of interest and value. Magnetism, or polarity, is, then, the expression of opposite properties on opposite sides. A bar of iron may thus be made to have positive or negative poles; but when the constraining power is removed the mobility of particles is such that they tend to equilibrium; while in the case of steel the rigidity of particles tends to a continuance of the binary tension in what we call a permanent magnet.

What, then, is electricity? It is polar motion, it is a continuance of that spiral interchange we have seen indicated in a reversed magnetic bar. As magnetism is polar tension, so electricity is polar motion. One is static as the other is dynamic. The all-pervading ethereal element, electron, electrine, or æther, is most commonly involved in the phenomena, but not necessarily, and whatever effects may be produced by ME, may also be referable to HO.

The simple or abstract view we have taken of battery action or of electrolysis may be true or it may not, but a lifelong study of the practice and theory of electricity prompts me to regard it as essentially, or in the main, a valid conception. But of apparently contradictory facts and varied complexities there is no end.

Our modern batteries do not derive more than half their power from the zinc consumption of the positive poles. Both sides or poles of the circuit are made to contribute to an augmented potential. These are varieties of detail which do not disturb the fundamental principles of action; and there is great danger in modern ways of becoming too clever, or getting lost in the multiplicity of facts and details.

If our simple view be scarcely recognisable in the books, it is much less so in the extended papers of modern electricians, where Helmholtz, Oliver Lodge, and others see opposite electrolytic ions travelling at different rates, and many other complexities which seem defiant of plain dual principles. But, alas! these are matters which can only be appreciated by a select few endowed with the highest attainments of modern education.

Which, then, is best? Should the great majority be silent and lose all manly independence in the cry "Great is Diana of the Ephesians!" or should they elect to make parallel efforts of equal magnitude in the prosecution of sound first principles with common sense reasonings, where both aspects might certainly render mutual aid?

Of the great abilities and love of truth of the eminent few there can be no doubt or question whatever; but Nature is impartial, and will best respond to those who seek her with humility and intelligence.

P.S.—It is, perhaps, right to add that between the hypotheses of mere force and electrolysis, Mr. Sprague, whose general views so closely accord with my own, has another hypothesis by which any idea of actual or material electricity is unnecessary; but his view is more hypothetic than mine, and has the disadvantage of being a special hypothesis rather than a general one.

He endorses my view of the liquid half, but on the metal side he thinks that the atoms turn round upon their neutral axes *without progression*, while in the liquid half the ions turn round, or exchange places *with progression.*

It is fair to consider that the same element may take part in both sides of the reaction, as with copper to wit; but how different must be the functions involved. In one case Cu is a + ion in connection with its − correlate; in the other it is both + and − in one, and turning round on its neutral axis.

But however incongruous this hypothesis may appear on further examination, yet many may prefer it as being more orthodox, with its two kinds of conduction, one with electrolysis, the other without. But time and further experiment will probably decide which is best in accordance with the truth.

P.S. 2—That electricity is in principle as material as water I have often contended in these pages, but Mr. Carl Hering, writing to the *Electrical World*, has expressed the fact with much of clearness and force. He says, "It is a well known fact that quantity of electricity measured in coulombs never is generated, never is consumed, and never does grow less, excepting leakage. The current flowing out of a lamp is exactly the same in quantity as that going into it; the same is true of motors and of generators, showing that electricity of itself is neither consumed while doing work nor is it generated. After doing work in a lamp or motor, it comes out in precisely the same quanoity as it entered. A battery is not able to generate quantity or coulombs of electricity, all it is able to do is to take the quantity which pours in at one pole, and sends out at the other pole with an increased pressure, or E.M.F. Electricity, therefore, is not merely force (or a form of energy), but matter. It is precisely analogous to water in a water circuit. The water is neither consumed nor generated. The pump merely increases the pressure of the water which flows in at one end. The water motor merely consumes the pressure, and converts it into mechanical work of another kind. It does not consume the water. The quantity of water, measured in units of quantity, is the same in all parts of a closed circuit of water, &c."

STUDENTS' CONVERSAZIONE AT THE FINSBURY TECHNICAL COLLEGE.

The *conversazione* given by the students at Finsbury Technical College on Friday evening last was attended by over 400 visitors, and proved to be a most successful and enjoyable affair. The building had been tastefully decorated throughout, and a large fountain illuminated by coloured arc and incandescent lamps played at the foot of the staircase. At eight o'clock Prof. Ayrton, F.R.S., delivered a most interesting and instructive lecture upon "Church Bells." It would, perhaps, have been difficult to have hit upon a subject better suited for such an occasion, and the numerous experiments—winding up with a charming performance by Mrs. Ayrton upon an instrument of the psaltery, sackbut, or dulcimer type—evoked great enthusiasm. At half-past nine o'clock this was followed by an equally interesting but somewhat more technical lecture on "Spectrum Analysis," by Prof. Meldola, F.R.S. By the aid of an electrical lantern some magnificent screen projections were displayed, the brilliancy of the effect greatly delighting the audience. In the meanwhile, in the second lecture hall an excellent musical programme was proceeding, which might also be heard by telephone in a distant part of the building. Those who sought instruction in preference to or in combination with amusement were also amply catered for. Mr. W. E. Sumpner, B.Sc. (a former student of the college, who has recently come prominently before the scientific world through his investigations on self and mutual induction), expounded and illustrated the use of the secohmeter.

The display of physical and chemical apparatus in the laboratories was of a most extensive character. Confining ourselves only to the electrical section, in addition to the large collection belonging to the College, the following companies and firms had sent exhibits, and we much regret that the limits of our space do not permit us to do more than catalogue their names:—The Gulcher Electric Lighting Company, Woodhouse and Rawson, Paterson and Cooper, Nalder Brothers and Co., Elliott Brothers, the Electrical Power and Storage Company, Shippey Brothers, Mark Bailey and Co., Goolden and Trotter, J. G. Statter and Co., Faraday and Son, Julius Sax, the Electrical Apparatus Company, Mayfield, Rogers, the General Electric Apparatus Company, A. Slatter and Co., Hodd and Co., and Hersch, Pritchard and Co. In conclusion, we must not omit to mention the "Trade" classes,

Digitized by Google

who exhibited some very creditable work, as did also the College Photographic Society. Altogether the display well exemplified the extent and importance of the work carried on at the institution, and all concerned are to be congratulated upon the eminently successful character of the results attained.

THE MEASUREMENT OF SELF-INDUCTION, MUTUAL INDUCTION, AND CAPACITY.

BY W. E. SUMPNER, B.SC.

(Concluded from page 213.)

SOME FURTHER RELATIONS BETWEEN THE NETWORK FUNCTIONS.

In the simple case of the Wheatstone bridge many relations follow from Lord Rayleigh's* theorem that if the current in any arm s of the bridge be C_s, and if $s+\sigma$ is the value of s for which the bridge will be balanced, the current through any branch of the bridge will be exactly as if the resistance s were increased to $s+\sigma$, provided we introduce into the new arm $(s+\sigma)$ an electromotive force $C_s\,\sigma$ acting in the direction of the current C_s.

Indeed, from the general fact that $\frac{R_{xy}}{R_{xz}}$ is independent of x, it follows that

$$\frac{R_{ss}}{R'_{ss}}=\frac{R_{sq}}{R'_{sq}}=\frac{R_{sb}}{R'_{sb}}=\frac{R_{sp}}{R'_{sp}}=\frac{R_{sq}}{R'_{sq}}=\frac{R_{sr}}{R'_{sr}},$$

where the quantities with a dash denote the corresponding quantities without a dash after we have substituted $s+\sigma$ for s in them.

Also, each of the above expressions is equal to $\frac{\Delta}{\Delta'}$, since

$$\Delta'=\Delta+\sigma B,$$

where

$$R_{ss}=\frac{\Delta}{B} \text{ and } R'_{ss}=\frac{\Delta'}{B}.$$

Moreover, for the Wheatstone bridge we know

$$R_{gb}=\frac{\Delta}{p\sigma} \qquad R'_{gb}=\infty$$

$$\therefore \frac{p\sigma}{\Delta}=\frac{1}{R_{gb}}=\frac{\sigma}{R_{sb}}\cdot\frac{1}{R'_{sg}}=\frac{\sigma}{R_{sg}}\cdot\frac{1}{R'_{sb}}$$

by the above-mentioned theorem.

It follows that Δ' breaks into factors—a fact easily verified, and one the statement of which is equivalent to Lord Rayleigh's theorem

$$\Delta'=p\,R'_{sg}\,R'_{sb},$$

or

$$p\Delta'=\Delta'_{sg}\,\Delta'_{sb}.$$

The same theorem gives—

$$\frac{1}{R_{sg}}=\frac{1}{R'_{sg}}+\frac{\sigma}{R_{ss}\,R'_{sg}}=\frac{1}{R'_{sg}}+\frac{\sigma}{R_{sg}}\frac{1}{R'_{ss}},$$

$$\frac{1}{R_{sb}}=\frac{1}{R'_{sb}}+\frac{\sigma}{R_{sb}}\frac{1}{R'_{ss}}=\frac{1}{R'_{sb}}\left(1+\frac{\sigma}{R_{ss}}\right),$$

$$\frac{\Delta'}{\Delta}=1+\frac{\sigma}{R_{ss}}=\frac{1}{1-\frac{\sigma}{R'_{ss}}},$$

$$\frac{1}{R_{bb}}=\frac{1}{R'_{bb}}+\frac{\sigma}{R_{bs}}\frac{1}{R'_{bs}};$$

and other relations can be written down.

The theorem stated above can be proved and generalised as follows:—

Let s be the resistance of any branch of any network of conductors; let E_s be the electromotive force, C_s the current, and V_s the difference of potentials of the extremities of the branch s. Suppose that E_s and V_s both tend to maintain the current C Then

$$s\,C_s=V_s+E_s.$$

If we have a second network which differs from the first only in the branch s we shall have

$$s'\,C'_s=V'_s+E'_s,$$

where, by supposition, $V_s=V'_s$, $C_s=C'_s$. This can only be the case when

$$E'_s-E_s=(s'-s)C_s.$$

If this relation holds, and if the resistances and electromotive forces of the second network differ only in the branch s, we shall have

$$V'_s-V_s=s'(C'_s-C_s).$$

If $C'_s=C_s$, the currents in corresponding parts of the two networks will be the same, for V_s and C_s being known the currents in the network outside s are perfectly determinate, and will be the same for the two cases if V_s and C_s are so.

Now suppose the change to take place in two parts.

First alter the electromotive force E_s: the current changes according to the equation

$$C''_s-C_s=\frac{E''_s}{R''_{ss}}-\frac{E_s}{R_{ss}},$$

since the change is entirely due to the change of the electromotive force E_s;

and

$$E''_s-E_s=R''_{ss}(C''_{ss}-C_s),$$

since

$$R''_{ss}=R_{ss}, \text{ by supposition.}$$

* "Determination of B.A. Unit," *Phil. Trans*, Part II., 1882, page 677.

Now suppose s be changed to s', so that R''_{ss} is changed to R'_{ss}, where $R'_{ss}-R''_{ss}=s'-s$: we have

$$C'_s-C''_s=\Sigma\frac{E_x}{R'_{xs}}-\Sigma\frac{E_x}{R''_{xs}}$$

$$=\Sigma\frac{E_x}{R'_{xs}}\left(1-\frac{R'_{xs}}{R''_{xs}}\right)=\Sigma\frac{E_x}{R'_{xs}}\left(1-\frac{R'_{ss}}{R''_{ss}}\right)$$

by (10); or

$$C'_s-C''_s=C'_s\left(1-\frac{R'_{ss}}{R''_{ss}}\right);$$

that is,

$$R''_{ss}\,C''_s=R'_{ss}\,C'_s.$$

Now suppose that $E''_s-E_s=(s'-s)C_s$:

then $E''_s-E_s=(R'_{ss}-R''_{ss})C_s$;

but $E''_s-E_s=R''_{ss}(C''_{ss}-C_s)$;

whence

$$R''_{ss}\,C''_{ss}=R'_{ss}\,C_s$$

$$=R'_{ss}\,C'_s,$$

or

$$C'_s=C_s.$$

Thus, if C_s be the current in any branch of any network of conductors, and if the resistance s of the branch be increased to s', the currents will be the same in every part of the network, provided an additional electromotive force be inserted in the branch s aiding the current and equal in amount to

$$(s'-s)\,C_s.$$

This is expressed analytically by the equation

$$\frac{1}{R_{xy}}=\frac{1}{R'_{xy}}+\frac{s'-s}{R_{xs}R'_{ys}} \qquad \ldots\ldots\ldots \quad (19)$$

x, y, s are any three branches of the network, any two or all three of which may be identical.

EXAMPLES.

Consider Maxwell's method of determining capacity (Vol. II., sec. 776). Suppose the commutator be placed in the arm s of the bridge. By equation (3) the formula is

$$\frac{E\,t}{R_{bg}}=2\,K\,V\left[\frac{s}{R_{sg}}\right]_{s=\infty}$$

where V is the highest potential to which the condenser rises. Now

$$V=\left[s\,C_s\right]_{s=\infty}=\left[\frac{s\,E}{R_{bs}}\right]_{s=\infty}$$

since this is the potential difference of the condenser when the commutator does not revolve. The derangement from balance is $\sigma=s'-s$, where $s'\,p=q\,r$; whence

$$\frac{1}{R_{sg}}=\frac{\Delta'}{\Delta}\frac{1}{R'_{sg}} \qquad \frac{1}{R_{sb}}=\frac{\Delta'}{\Delta}\frac{1}{R'_{sb}}.$$

Now

$$\frac{\Delta'}{\Delta}=\frac{1}{1-\frac{\sigma}{R'_{ss}}}=\left(1+\frac{\sigma}{R_{ss}}\right);$$

whence

$$\frac{t}{R_{bg}}=\frac{2\,K}{R'_{sg}\,R'_{sb}}\times\left[\frac{s^2}{\left(1-\frac{\sigma}{R'_{ss}}\right)^2}\right]_{s=\infty}=\frac{2\,K}{R'_{sg}\,R'_{sb}}(R'_{ss})^2.$$

Now

$$\frac{1}{R_{bg}}=\frac{1}{R'_{sg}}\left[\frac{s}{R_{sb}}\right]_{s=\infty}=\frac{R'_{ss}}{R'_{sg}\,R'_{sb}}.$$

Substitute, and we get

$$K=\frac{t}{2\,R'_{ss}}=\frac{t}{2}\frac{\text{coefficient of } s' \text{ in } \Delta'}{\Delta'},$$

which is Maxwell's solution.

By writing out the value of R'_{ss} as above defined, and remembering that Δ' breaks into factors, this formula will be found identical with that given by Professor J. J. Thomson.

Self induction of the galvanometer has no effect whether the condenser gets fully charged or not. Professor Ayrton has noticed the misprint of a for α in Maxwell (Vol. II., sec. 776).

As another example, take Ayrton and Perry's method of determining self and mutual induction.

Integrating equation (2), during the time t that the galvanometer and battery are on together we have in this case

$$Q_1=\frac{E\,t}{R_{bg}}-\frac{1}{R_{sg}}\left\{\frac{E\,L_s}{R_{sb}}+\frac{E\,M_{sb}}{R_{bb}}\right\}-\frac{1}{R_{bg}}\left\{\frac{E\,L_b}{R_{bb}}+\frac{E\,M_{sb}}{R_{bs}}\right\}-\frac{1}{R_{gg}}\frac{E\,L_g}{R_{bg}}.$$

While the galvanometer is short-circuited the additional quantity which rushes through is

$$Q_2=+\frac{1}{g}\frac{E\,L_g}{R_{bg}},$$

since g is the new value of R_{gg}. Thus the quantity Q_1-Q_2 passing through the galvanometer in each cycle is zero if

$$t+\frac{L_g}{g}-\frac{L_g}{R_{gg}}-\frac{L_b}{R_{bb}}-\frac{M_{sb}}{R_{sb}}=\frac{R_{bg}}{R_{sg}R_{sb}}L_s+\frac{R_{bg}}{R_{sg}R_{bb}}M_{sb}.$$

Now

$$\frac{R_{bg}}{R_{sg}\,R_{sb}}=\frac{R_{bs}\,R'_{sg}}{R_{sg}\,R_{sb}}\frac{1}{\sigma}=\frac{R'_{sg}}{\sigma\,R_{sg}}=\frac{\Delta'}{\sigma\,\Delta}=\frac{1+\frac{\sigma}{R_{ss}}}{\sigma}$$

since

$$\frac{1}{R_{bg}}=\frac{\sigma}{R_{bs}\,R'_{sg}};$$

Digitized by Google

moreover, $$\frac{R_{bg}}{R_{sg}R_{bb}} = \frac{1}{\sigma}\frac{R_{bs}R'_{sg}}{R_{bb}R_{sg}} = \frac{\Delta'}{\Delta\sigma}\left\{\frac{R_{bs}}{R'_{bb}} + \sigma\frac{R_{bs}}{R_{bs}R'_{bs}}\right\}$$
$$= \frac{1}{\sigma}\left\{\frac{R'_{bs}}{R'_{bb}} + \frac{\sigma}{R_{bs}}\right\} = \frac{1}{\sigma}\left\{\frac{p+r}{p} + \frac{\sigma}{R_{bs}}\right\};$$

whence we obtain

$$L + \frac{p+r}{p}M_{sb} = \sigma t + \sigma\left\{\frac{L_{sg}}{g} - \frac{L_{sg}}{R_{gg}} - \frac{L_b}{R_{bb}} - \frac{L_s}{R_{ss}} - \frac{2M_{sb}}{R_{sb}}\right\}.$$

This solution is identical with that worked out in Ayrton and Perry's paper.

For the method indicated by Fig. 17 we have, if X be joined to C,

$$Q_e = \frac{Et}{R_{bg}} \qquad Q_p = \frac{M_{rb}E}{R_{bb}R_{rg}} + \frac{M_{rb}E}{R_{bg}R_{br}} - \frac{L_{sg}E}{R_{bg}R_{gg}} - \frac{L_{sg}E}{gR_{bg}},$$

where t is the time in a cycle during which the galvanometer and battery are on together. We get for balance

$$\frac{s+q}{s}M_{rb} = -(p+r)t - (p+r)\left(\frac{L_{sg}}{g} - \frac{L_{sg}}{R_{gg}} - \frac{2M_{rb}}{R_{rb}}\right)$$

and indeed this formula might have been deducted from the preceding, since the derangement from balance is

$$-(p+r).$$

For the method indicated in Fig. 18 we have, in the case where r is infinite,

$$Q_e + Q_k = \frac{Et_1}{R_{bg}} + KE\rho_1\left(\frac{b_2}{R_{bb}} + \frac{g}{R_{bg}}\right),$$

where t_1 is the time of charging;

$$Q_e + Q_k = \frac{Et_2}{R_{bg}} - KE\rho_2\left(\frac{b_2}{R_{bb}} + \frac{g}{R_{bg}}\right),$$

where t_2 is the time of discharging. The whole quantity is zero if

$$t_1 + t_2 = K(\rho_2 - \rho_1)\left\{b_2\frac{s+q+g}{s} + g\right\},$$

where, if we imagine the condenser replaced by a battery, the proportion of the current through the galvanometer to that through the battery will be ρ_1 when the free end of the battery is connected with the wire b_2, and ρ_2 when it is connected with the galvanometer. Now, generally, s will be small compared with b_2 or with q, so that ρ_1 may be neglected compared with ρ_2, and

$$\rho_2 = \frac{s+q}{g+s+q}, \text{ practically;}$$

so that

$$K = \frac{s}{qb_2}t,$$

where t is the period of the commutator.

If a vibrating tuning fork be used to commutate the connections t will be very small, and the formula must be more fully worked out.

For the case of Fig. 9, when the resistance s is infinite, we have for balance the condition

$$\frac{Et}{R_{bg}} = KV\left[\frac{s}{R_{sg}}\right]_{s=\infty}$$

neglecting the self-induction of the galvanometer, V being the potential difference to which the condenser rises, and, as before,

$$V = \left[sC_s\right]_{s=\infty} = E\left[\frac{s}{R_{sb}}\right]_{s=\infty}$$

and, as in Clerk Maxwell's method, we get

$$t = KR'_{ss};$$

in fact, the method is essentially the same as that of Maxwell. Its connection with Maxwell's method of determining self-induction (see Fig. 7) is clearly shown by deducing one formula from the other.

We have for self-induction—

$$L_s = \frac{qr - ps}{p}\left(t + \frac{L_{sg}}{g} - \frac{L_{sg}}{R_{gg}} - \frac{L_{ss}}{R_{ss}}\right);$$

we have for capacity—

$$-s^2K_s = \frac{qr - ps}{p}\left(t + \frac{L_{sg}}{g} - \frac{L_g}{R_{gg}} + \frac{s^2K_s}{R_{ss}}\right).$$

Now $R_{ss} = s + R_{os} = s + R_2$, using Maxwell's notation;

also, $$\frac{ps - qr}{p} = s - R_1 \qquad ,, \qquad ,,$$

whence $$\frac{s^2K_s}{(s-R_1)(s+R_2)}(R_1+R_2) = t + \frac{L_{sg}}{g} - \frac{L_g}{R_{gg}}.$$

Now make s infinite, and we have

$$K_s(R_1+R_2) = t + L_{sg}\left(\frac{1}{g} - \frac{1}{R_{gg}}\right).$$

The foregoing examples are sufficient to show the ease with which the solutions of network problems may be obtained in terms of the resistance functions. For such problems these functions possess the same two advantages over determinants that determinants possess over common symbols. The first is that complex quantities are expressed in a simple way and analysis is rendered more rapid. The second is that if the solution is of a simple nature it must be possible to eliminate the complex quantities by making use of the relations between them, while if the solution is complex all that can be gained is the power of expressing the result in a simple manner.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirtieth half-yearly general meeting of the shareholders of this Company was held on Thursday, July 14th, 1887, under the presidency of John Pender, Esq.

The SECRETARY read the notice convening this meeting, and the minutes of the last general meeting.

The CHAIRMAN: Gentlemen, before asking you to approve of the accounts I will, as usual, make some remarks upon them and upon the business of the last half year. The revenue for the six months ending on the 31st March, 1887, amounted to £331,862, against £341,405, or a decrease of £9,543. The balance brought forward from last half year's accounts is £19,458 less than in 1886, so that we now have to deal with the sum of £28,902 less than at this time last year. The total working expenses amounted to £33,035, against £92,241, or a decrease of £9,209. This, in a measure, arises from the absence of those extraordinary expenses which are unavoidable in time of war. The general expenses in London were £8,169, against £8,773, or a decrease of £604. The principal decreases took place in office expenses, rent, taxes, lighting, stationery and printing, and repairs of furniture. Working expenses at the stations were £60,674, against £64,439. Most of the items under this head show a considerable decrease, the net reductions in station expenses, as compared with the corresponding period of 1886, being £3,765. The expenses attending the repairs and renewals of cables were £43,903, against £41,637, or an increase of £2,266. One of the items in this account is for the completion of the repairs to the Direct Lisbon cable, which is now nearly entirely new. One of the Company's ships, the screw steamer "John Pender," has been fitted with new boilers, improved electric light, thoroughly overhauled and re-classed at Lloyd's. The expenses of carrying out this work, together with the extensive alterations made to the hull, and picking up the gear, &c., of the unfortunate screw steamer "Volta," has been charged to the maintenance ships fund. We have laid in the last six months 135 miles of new cable. Notwithstanding the reductions in revenue to which I have referred, it is satisfactory to find that after charging all expenses, including income-tax, providing for interest on debentures, debenture stock and preference shares, we are still able to pay a dividend and bonus on the ordinary shares at the rate of 5½ per cent. for the year, and to carry forward £48,000 to the general reserve fund. Gentlemen, these are the main and striking points in the accounts, and I shall now give you some general remarks upon what has occurred since I had the pleasure of addressing you in January. When I then had the pleasure of addressing you we had been paying a bonus for some two or three years. I stated that the reductions which were forced upon us at Berlin took away something like £40,000, and that that practically did away with our bonus. I think I shadowed forth at the same time that in all probability—believing that there was a recouping influence at work in our telegraph system—we hoped that the year would not pass without, at any rate, our paying some portion, if not all, of the bonus. Singularly, during the first few months of the reduction in the rates, instead of there being an increase in our traffic it rather went back. However, that was temporary, and I am glad to say that in the last two or three months things have come right again, and that we are enabled to-day to redeem my promise, because for the last half-year we are going to pay you the usual bonus, which has been at the rate of ½ per cent. for the six months. I hope this will be satisfactory to the body of shareholders. It ought to be satisfactory in this, that while we have met a large public demand for lower rates, we have returned to paying our shareholders what we believe they are very fairly and honestly entitled to—a bonus in this great and important enterprise. I think you will admit that this, upon the whole, is a satisfactory statement.

Since I last had the pleasure of addressing you we have connected Tangiers with our cable system at Gibraltar. We found there was a great public want required there. We were requested to do this work, and we did it, and I am very glad to say that it has proved a satisfactory connection. The cable is working well, and the return is much in advance of what we anticipated. That is another feeder to this great system, which will bring in a few thousands a year. The Italian Government have also, under our more immediate eye, laid a cable from Massowah and Assab, connecting it with our station at Perim. That will be an additional feeder to our system. That has also been been satisfactory. We undertook to protect it for three months, I think, and we got about £5,000 for doing the work. It is very satisfactory for me to tell you that there was no work required from us.

There is a further important question which I shadowed forth on the last occasion of our meeting. I said that to make ourselves thoroughly independent of our land line system through France it might be necessary to lay another cable from the Land's End to Gibraltar and Malta. Looking to the state of affairs on the Continent, probably we have not undertaken to do this work one day too soon. Anybody reading *The Times* of to-day must have been struck with the critical position in which Europe is at the present moment. It has always been the policy of your Board to be ahead in their work—that is to say, we are free to act, and we believe we have the support of our shareholders in thus acting as long as we can see our way to maintain our dividend. We see our way in doing this work to saddle the undertaking with but a very slight additional amount of capital, and we say that the independence that will give us for maintaining our dividend is a result which justifies us in doing this work. We have had a line through France for some years, and we have occupied that line very considerably. We have felt that it was not a safe line to rely upon. We have had difficulties thrown in our way on the part of the French Government to renewing that concession. We thought it was well, therefore, to take time by the forelock. Although we have applied to our Government to assist us in this work we

Digitized by Google

have only had the response that at the moment, so far as they were concerned, it was not considered necessary. However, we have before anticipated the wants of the Government, and we believe we are anticipating the wants of the Government and of the nation at the present moment, and in doing so I believe we are adding immensely to the stability and position of this telegraph company. That line will be laid and working within the next two months. It may be laid sooner if desired, and it will secure to us, should any interruption take place in our French system to-morrow, all that we at present obtain by our line through France. It will also secure to us a great addition to our carrying power, which is required from the reduction of rates which is taking place now, and which is likely to take place all over the world. As I have said before, our policy is to be ahead, not behind, the wants of the country and of telegraph people, and I can safely say that in carrying out this cable we are carrying out the policy which has made the Company what it is at the present moment—a Company so strong in itself that I believe it is impossible to attack it in any way on the ground that we are not doing our work efficiently and well. I have told you a straight story about this work. We have intimated to our Government that if at any time they require a preferential working of that cable—and I believe the time may come when they will require it—what they will have to pay for it. I think what we have done will commend itself to the Government, as I am pleased to find it commends itself to our shareholders.

We have had during the last six months a very melancholy event. We have lost another steamer, and we cannot understand how that loss could possibly have taken place. It can only be on the plea that the captain and officers of this ship "Volta" were so accustomed to sailing among the islands of the Greek Archipelago that they had got to believe the ship could take care of itself. The captain has gone, he did his work admirably for us, and how he made such a mistake in taking his vessel on the rocks instead of taking her through the proper channel I cannot understand. However, I am pleased to tell you that the Board of Trade, having made a very careful inquiry, have relieved the Company from all blame. We are not held in any way responsible for the act. The ship was reported by the Board of Trade to have been in the most efficient condition. There is nothing wanting in our ships to do our work well, and while we were complimented by the Board of Trade on the efficiency of that ship our captain was evidently at fault. It has resulted in no pecuniary loss to the Company. The insurance money has paid for the new ship we are now building to replace the vessel that has been lost. All possible modern improvements will be introduced, and I hope we are acquiring a ship that will work probably more economically than the one which we have just lost.

There is another question which it is right I should mention, that is, we are replacing our 5 per cent. debentures, which expire on the 1st of August next, by a 4 per cent. stock. I am glad to say that that has been pretty freely taken up by those who hold our 5 per cent debentures. This will effect a certain saving to the Company. But it does more than effect a saving; it shows the solid position in which this Company is considered to be by the investing public. I think from the early days—and this is the 30th half-yearly meeting, I believe, that I have addressed—I have always said that this was a property the importance and value of which we had yet to learn. Every year has taught us that we control it and command it. If a fault occurs to-day, within a few days we may say almost to a certainty that that fault will be repaired. Therefore, we have established what now may be called a permanent property, and it is being so viewed when this 4 per cent. debenture stock is being so freely taken up. I think that is a compliment to the Company. I am glad to find that not only is our property good as to our cables, but I believe that our credit is equally good. I may say that should there be any amount of this 4 per cent. stock not taken up by those who hold the 5 per cent. debentues, or if there are any parties who do not hold those debentures and who wish to take this stock will send in their names, we will consider the applications they make for any portion of the stock not taken up by the holders of the present debentures. I would just, in closing these remarks, refer to this great year in the history of England—the Jubilee of the Queen. I may say, in regard to this period of 50 years, that it is during the last 20 years that submarine telegraphy has been established and brought up to its present position; and probably nothing has been done during the reign of Her Majesty that has left a greater mark upon human progress than this submarine system of telegraphy. People talk of confederation. I say that this system has been the means of bringing about a great moral confederation. It has brought our colonies and the mother country into daily, almost hourly, communication, and the result is that we find throughout our colonies an amount of loyalty—aye, loyalty exceeding that which we see at home. I think we may congratulate ourselves as a company on the great work we have done, and I trust that that work will continue, and that when the days of war scares come round the telegraph will play an important part in preventing war, and that if war does occur it will play a still more important work in bringing it to a close. With these remarks I beg to move the following resolution:—

"*That the printed report and accounts of the Directors to the 31st March, 1887, submitted to this meeting be, and the same are hereby received and adopted; that a dividend on the preference shares of the Company to the 30th June, 1887, at the rate of 6 per cent. per annum be paid, less income-tax, and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 1s. per share, both free of income-tax, on the ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 5½ per cent. on these shares for the year ended 31st March, 1887.*"

Mr. G. G. NICOL: I beg to second that.

The CHAIRMAN: If any gentlemen desires to put any question to me, or make any remarks on the report, I shall be very glad to hear him before I put the resolution.

Mr. JOHN NEWTON: May I ask a question? Would you mind telling us what is the difference in the security between the five per cent. debentures and the stock which the holders have now the option of exchanging for? We naturally look for a higher security, seeing that we are going to take a step lower in the rate of interest payable. Do you mind telling us how many debentures have been exchanged up to the present time?

The CHAIRMAN: I think, Mr. Newton, there is no use in dealing with a half-finished job. I shall be able as soon as the time expires to tell you. We have given a time, after which applications by the debenture holders to make the exchange for this new stock must cease. That time is the 16th of July, and I will then tell you exactly how we stand in that matter. As to the security, the new security is precisely the same as that which it is taking the place of. The solicitor corrects me. The new security is to be a permanent security. The other one was a terminable security, and the permanent security will be a first charge upon the Company's undertaking. As I have often said to you, in all these matters we are guided by precedents, and we are also guided by the reports of our solicitors and accountants. If you wish for any further information on the subject—what I call technical information—Mr. Burt will be very glad to tell you exactly what the security is; but I think I have given you pretty well the gist of it.

The SOLICITOR: I think it would be satisfactory to all the shareholders if I were to answer Mr. Newton's question in a little more detail. The present security of the debenture holders is simply a bond or obligation of the Company to pay the money at the time named. It is a fixed date, and the Company has to pay that sum at that fixed date, but it has no charge upon the property or revenues of the Company—no specific charge. It is an obligation, a debt, of the Company, but it is not a specific charge on the property. With respect to the mortgage debenture stock, which, as Mr. Newton says, is 4 per cent., the debentures bearing 5 per cent., that is expressly made a first charge on the undertaking and property of the Company. The special resolution expressly says, "That the Board of Directors be and are hereby authorised from time to time to create and issue mortgage debenture stock of the Company to an amount not exceeding one-third of the share capital of the Company for the time being issued and paid up, upon the terms that the aggregate amount of the said stock for the time being in issue, and the interest thereon, shall rank *pari passu* as a first charge on the undertaking and revenue of the Company." Therefore the holders of mortgage debenture stock do have a settled and higher class of security than the holders of the debentures. The interest, as Mr. Newton says, is less, but the security of both, I think, is very ample.

Mr. NEWTON: The answer which the solicitor has given I am very much obliged for. I think it is necessary when a company is issuing any kind of bond or security to which they attach the word "mortgage" it should be explicitly understood by the investor. It is by using such terms as that when there is no mortgage that the public are deceived. I have a security now in another company where the term "mortgage" is used, and it is no mortgage at all. Seeing the correspondence in the papers recently in reference to these first charges, calling them mortgages, it is an advantage to this Company to say what is the exact security offered to those who are probably putting trust money in this property. I have held these 5 per cent. debentures since they were issued, and I have been very pleased with my security. While I am pleased to see telegraph property ranking as it ought to have ranked years ago, I do not, as an individual investor, like to go from 5 per cent. to 4 per cent. without the fullest information. I thank you for your information.

Mr. GRIFFITH: I think after Mr. Burt's statement that even our very able business friend Mr. Newton may be satisfied with the character of the security. As a shareholder I was rather struck that while our late debentures were merely a temporary obligation, this new stock will be permanent. That is the interpretation that I put on Mr. Burt's statement.

The SOLICITOR: Certainly.

Mr. GRIFFITH: And that we have not the power of paying it off?

The SOLICITOR: Yes, you can buy up this stock, but not call it in.

Mr. GRIFFITH: That is the same thing under a different name; but certainly it is an advantage to the new debenture holders that they should have a direct charge on the Company—that it should be a mortgage. I only hope that the burden on us will not be a permanent one, and that we shall not have an encumbrance for any length of time. You said that our property is now becoming of a permanent character, permanent in its nature, permanent in its prosperity, permanent in its influence, and I hope sincerely in the good fruit that it will produce. At the commencement of your speech you said it was matter of congratulation that we should receive 5½ per cent. this time. Congratulation is rather a term of degree, and I should have been pleased had we kept up the old dividend. The present distribution may be satisfactory, but the old one would have been still more satisfactory. Our capital is increasing largely. We have a large income from the African Company, and also from the Black Sea Company, and when our traffic is increasing to such an extent it does seem right that the holders of the property should receive an increased instead of a diminished return. At the same time I am aware that we are all creatures of circumstances. This Berlin Conference that you spoke of may be a most potent power in the management of the telegraphs; but I was sorry to hear the expression you used, that you were "forced" to come into the terms which were imposed by this Conference. The word "forced" is somewhat abnormal. It may be that they used some undue influence with you, or that they possessed some power by which they could use influence with you in regard to the cables. The shareholders consider it would be their duty to support the Directors in opposing any improper force which tends to decrease the income, and therefore their dividends. This new cable to which you have alluded may be one of the most statesman-

Digitized by Google

like operations that could be conceived; but I do not think we should give in to the outside public, and that while we increase the facilities for business ws should lower the profit we are entitled to receive. If our property is so permanent in its character, power, and influence, it does seem proper that our shareholders should share in its increased prosperity, and that the increased profits should not be as a rule surrendered to others unless overwhelming force compels it.

Mr. HUSBAND: Before you answer I want to ask you a question with respect to the new line that is to bs laid to Gibraltar. I was going to ask first of all with what money the line is to be laid, whether it is to be laid out of the reserve fund, and I also wish to ask how much it will cost? In relation to the remarks made by the gentleman who has just sat down, in comparing the dividend of 5½ per cent. with 6 per cent. that we had once, one reason why it seems to me reasonable to expect that we should at least keep up the dividend is the fact that we have so large a reserve fund. I see that we have in money £564,000 of reserve capital; but in addition to that I find by our accounts—this is on page 6 of the report—there is a duplicate cable in the Red Sea and Indian Ocean representing £100,000, there is a triplicate Red Sea and other cables representing £300,000, and these, so far as I can see, are made out of the £448,000, which is itself reserve fund, and which is therefore costing no interest, either as debenture or as dividend. It seems, assisted as you are by a million of money and the money's worth in your reserve fund, that to keep up the dividend at 6 per cent. would not entitle the Directors to the credit of having done anything superlatively meritorious. I have no doubt that you will answer my first question, at any rate, as to what is to pay for the new line to Gibraltar, and also what the amount is that it is to cost; and perhaps you would also go the length of saying what dividend you expect that line to make when it is laid.

Mr. FOWLER: There is one question I should like to ask arising out of a remark made as to the issue of their capital. I understood you to say the capital would not be materially increased, which means that it will be increased. I would venture to ask whether that additional capital will be offered in the first instance to the existing shareholders *pro rata* according to their holdings. I presume the capital will be partly ordinary and partly preference, as the Directors may think convenient. I only wish to know if the existing shareholders will be offered their proportion of the capital first.

Mr. BAINES: I was going to ask a question—it is perhaps important to the Company's interests—whether in the event of your negotiations with the French Government as to renewing your concession with them failing—whether any loss of time will be made in transmitting messages by the altered route?

The CHAIRMAN: First I have to thank Mr. Newton for bringing the question of the security of our new debentures before the shareholders, and I think he will be pleased with the reply of our solicitor. You are getting better security for your 4 per cent. than you had for your 5 per cent. In regard to Mr. Griffith's remarks, it is always very pleasant to keep up the full extent of your dividend, but you must remember when we established the bonus principle I stated to the shareholders that we would consider the 5 per cent. as our dividend, and that when we could pay bonuses we would do so—that the bonus was not to be looked upon as a permanent thing, but that it should be of a fluctuating character, and be 1 per cent. for the year, or 2 per cent., or ½ per cent., according to circumstances. I merely mention that to show you that the bonus is distinct from the dividend. The reason that we did not pay ½ per cent. for the first half year was that at Berlin an alteration took place in the land line systems by which the European Governments, with their long purses behind them, came to an arrangement which obliged us to alter our tariff. We were forced, therefore, to reduce our rates, and that amounted to £40,000 a year. That wiped away for the time our bonus, and now, with time going on, we are to a certain extent recouping our lost traffic. I hope next half-year we may again pay our ½ per cent., and therefore take up the position of paying our bonus, but still as distinct from paying our dividend. There will be great fluctuations in telegraph property. There must be. It is an uncertain property, I say, still; but at the same time we know in our shallow water where we can pick up a cable, and we are doing it every day. Demands, however, may come upon us at any time, and we must keep ahead of the wants of the Government and of the country, and in keeping ahead of these wants we have received great and important consideration from the Government. For instance, we had the exclusive right for a very considerable number of years of landing cables in Egypt. That is an advantage to this Company which is worth almost untold money, particularly when you look to the fact of the competition in connection with the Atlantic cables at the present moment, for those companies are paying practically no dividend at all. It has been our object so to make our arrangements as to regulate our traffic, and maintain a respectable dividend, and a permanent dividend, and that we have done up to the present time. I would say to Mr. Griffith that we cannot stand still. That would be impossible. If we were to stand still we must go back. There is an increasing demand one way or another, and we must, as far as possible, meet that demand, and be ahead of it. Replying to Mr. Husband, the Chairman explained how the Company proposed to pay for the new cable without materially increasing the capital account. I am looking forward to a very large increase in the traffic. I think it must come, looking to the arrangements likely to be made with Australia for lower rates. Therefore, with our new cable down we are quite independent of France. Still, if France is reasonable—they do not show a very good disposition to meet us up to this moment—yet if next year, when our concession expires with the French Government, they say that we shall hold the cable, it will be an advantage, looking forward to this expected increase of traffic. This will give us an alternative line. I think these remarks will satisfy you that we are reducing the expenses of the new cable to a minimum. We are going to pay towards that cable what we pay to the French Government and other companies at the present moment, and I hope that that will be satisfactory to you. Mr. Fowler asked if we are prepared to give the shareholders *pro rata* the option to subscribe to the capital we shall require for the new cable. I assure you we are going to finance that so as practically to add nothing to the capital. I am as far as possible against adding to the capital, but I think you should be more satisfied with a permanent 5 per cent. and an occasional bonus now and then than leaving our system to drift and competition to arise, and permitting your dividends to be reduced to a mere nominal amount. It is our business to do our work so well that neither Governments nor the outside public will try to tread upon our ground. I was asked if there would be any delay in transmitting the messages. Our arrangement with France goes up to next year; but France may be in a blaze to-morrow for what I know. Judging from what we read in *The Times* the state of things looks very alarming. At all events, to show you how much alive we are to the position—though we do not talk about it, as we do not want to add to scares—the ship is now at Porthcurnow with a large amount of cable on board, and, I believe, could lay the cable in a month.

Mr. NEWTON: Will you compete with your new cable with the Direct Spanish? We are all one company.

The CHAIRMAN: We do not lose sight of that. We are even anxious now to come to an arrangement with Spain. Our negotiations, indeed, are so far advanced that we shall have one of these days an alternative line from Bilbao to Barcelona connected with our system, and from Barcelona we shall connect with our main system at Gibraltar at very small expense. That would give us another line. "Sufficient for the day," however. We have it all in view, and are losing sight of nothing, our desire being to place our Company, in the event of war, in such a position that it will be able to meet, not only public requirements but Government requirements as well. The resolution has been moved and seconded, and with these few remarks I now put it. Those in favour of the motion hold up their hands. To the contrary. Carried unanimously. That closes the meeting.

Major LESLIE: Will you let me move a vote of thanks to our Chairman? I think we must be all very much pleased and gratified at hearing such an eloquent and pleasing statement on our position, and the success we have achieved in attaining to such a fair dividend. After the loss that was caused to us through the action of the Powers of Europe, I think what has been done for us deserves our best thanks.

Mr. GRIFFITH: I shall be happy to second the motion. I am sure that the shareholders will support the Directors whenever any improper action is brought against us by the Governments, with their long purses. We are indebted to Mr. Pender for the kind way in which he has answered our questions. We are indebted to him also for the great experience and skill which he has displayed in the management of the Company, and I certainly cordially support the proposal that we tender a vote of thanks to Mr. Pender and his colleagues.

Major LESLIE put the motion, and it was carried unanimously.

The CHAIRMAN: Gentlemen, it is the greatest possible pleasure to my colleagues and myself to have an expression of the renewed confidence of the shareholders. You may rest assured that the experience we have gathered over many years, as well as the position we have attained, has arisen in a great measure from the confidence which the shareholders have shown in us from time to time at these half-yearly meetings. We have had to-day one of our most severe critics with us. We have a great deal more experience here to-day than we had a few years ago. We have been always glad to have hints given to us, and we have never lost sight of them, and where we have thought they were right and proper we have taken advantage of them. The result is that the position which this Company occupies to-day is second to that of no other telegraph system in the world, and it will continue to receive our most careful attention. We find those who came at first to be severe on us now come to compliment us. That is our reward. We are much obliged to you for your attendance here to-day.

The proceedings then terminated.

The Telegraph Construction and Maintenance Company (Limited).

The half-yearly general meeting of this Company was held on Tuesday, at the offices, 38, Old Broad-street, E.C., Sir George Elliot, M.P., in the chair.

Mr. WILLIAM SHUTER (the Manager) having read the notice convening the meeting,

The CHAIRMAN said: At the request of my colleagues I occupy the chair owing to the absence of our worthy and highly esteemed chairman, Sir Daniel Gooch, who has had a slight accident. I am very thankful and glad to say that I believe it is only slight, but sufficient, I believe, to confine him for a few days. We should all very deeply regret the loss of the useful attention of so valuable a colleague as our Chairman. Well, now, as to the business before the meeting, this is really practically so insignificant that were it not for the purpose of the shareholders keeping touch as it were with what is going on from time to time these half-yearly meetings, which were instituted some years ago, might be dispensed with. At the same time we are very glad to see all of you here, and I will just point out that which will appear to be the only business with which we have to make you acquainted. It is the work done for the half year under contract. We have connected the Italian ports in the Red Sea with Aden, using 359 miles of cable—that is one thing done. The next thing is we have repaired the German Union Company's cable in the North Sea. With regard to the more important work which we are now engaged upon, the "Scotia," which is one of our excellent ships, the property of the Company (we have not to charter vessels now) left England on the 11th inst. with 1,300 miles of cable on board to con-

Digitized by Google

nect the Land's End with Lisbon and Gibraltar, and she is now carrying out that work. Submarine telegraph companies find it almost necessary to duplicate their lines, and wherever there is one cable another in course of time is required. That is very much what constitutes the life, as it were, of this Telegraph Construction Company, to go on developing and replacing, and I hope it will continue so for many years. I do not know that I have more to report to you than merely mention these facts. We are hopeful that we shall continue to satisfy the shareholders; at the same time we have a very great staff, and we are desirous to be employed, and we are not without prospect that that may be continued to us. I believe there is no resolution to submit; it is merely that we come to see you, and so long as we can go on paying our dividends I am sure we will always be quite certain to have your confidence, and that is what the business is, not to have too much curiosity or prying into what is being done, but to be satisfied with a good dividend.

A SHAREHOLDER: I am sure I am only expressing the regret of all the shareholders at the intelligence we have from you (and which we knew for ourselves) as to the accident which has befallen the worthy Chairman. You may recollect at the last half-yearly meeting I asked some questions of the Chairman with regard to the electric light, and the Chairman very properly, if I may say so, declined to say anything on the ground that an action was then pending, and which was shortly to be brought to a conclusion. That action has now come to an end favourably to this Company, I believe, and I think the shareholders would be glad to know, Sir, from you, if you can tell them, in the absence of the Chairman, whether you propose to take any steps in developing the electric light through the medium of this Company?

The CHAIRMAN: The hon. shareholder has asked a question which I think is very pertinent; the litigation has been successful. It was resisted by the Great Western Railway; it is not our litigation, we were not subject to its costs, and it has been terminated favourably. We have before us there, what was contemplated, a great example of what can be done, and I believe it is the subject of serious consideration with the Directors what use and how far the experiment may be utilised in connection with the development of the business of this Company. I hope that answer will be satisfactory to everyone. We hope it may become useful, and that we may be able to do any work in connection with electricity, so far as we are concerned with the materials we have, that may be required. I do not know that there is anything more.

Mr. WILLIAM SHUTER: If you will allow me I will read this notice relative to the Second Bonus Trust:—"The Second Bonus Trust (which formed part of the dividend paid to shareholders on the Company's register in February, 1885), the trustees having realised the balance of shares constituting the trust, the above certificates, with Coupon No. 24 attached, are now being paid off at the rate of £1. 7s. per £5 nominal value (£2. 10s. being paid off in August, 1881). Capital unclaimed at Messrs. Barclay's Bank:—First distribution about £1,000, Second and Final £11,000, Coupons £500." That will go forward in the report, and I hope the claims will come forward.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

A meeting of the shareholders in this Company was held on Tuesday, at the Cannon-street Hotel, Mr. S. W. Silver presiding.

The SECRETARY (Mr. W. J. Tyler) having read the notice convening the meeting,

The CHAIRMAN said: The shareholders will be aware that the books of the Company are not made up until the close of the year. They will not be surprised to hear from me that the same keen competition that has already been alluded to is still met with by the Company as a trading concern, and I need scarcely remind you that that state of things requires on the part of the managers and others the greatest possible attention to effect sales, which I hope, when the books are made up, will be found to justify the motion which I now beg to propose, namely, "That an interim dividend of 5 per cent., or 10s. a share, free of income-tax, be payable on and after the 20th inst."

Mr. NEIL BANNATYNE seconded the motion, which was carried unanimously, and a vote of thanks to the Chairman and Directors having been cordially passed, the proceedings terminated.

Anglo-American Telegraph Company (Limited).

Report of the Directors to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, 27th inst., at half-past one o'clock:—

The total receipts from the 1st January to the 30th June, 1887, are estimated at £100,534. 9s. 3d. This amount, however, is subject to revision, dependent upon the result of the law-suit now pending between this Company (on behalf of the associated Atlantic cable companies) and the Paris and New York Telegraph Company. The traffic receipts show a decrease as compared with the corresponding period of last year of £16,492 consequent upon competition, a reduced tariff, and the fact that from 1st January to 4th May, 1886, the 1s. 8d. rate was in force. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £47,211. 2s. 7d. One quarterly interim dividend of 5s. per cent. on the ordinary stock, and of 10s. per cent. on the preferred stock, was paid on the 1st May, 1887, absorbing £17,500, and second quarterly dividends of similar amounts will be distributed on the 30th July, 1887, leaving an estimated balance of £18,323. 6s. 8d. to be carried forward to the next account. The Company's repairing ss. "Minia" has been engaged during the past half-year in the repair of the 1873 cable off Valentia, Ireland, and the St. Pierre Duxbury cable off Seal Island, Nova Scotia. She has also executed three repairs for the Direct U.S. Cable Company and two for the Western Union Telegraph Company, the remuneration for which will be found in the revenue account. The Company's system of cables and land wires is in good working order, with the exception of the Brest St. Pierre and St. Pierre Duxbury cables, the former of which was broken in deep water at a distance of 600 miles from Saint Pierre on the 9th November, 1886, and the latter in shallow water at a distance of 380 miles from Duxbury on the 15th June, 1887. The Company's ss. "Minia" left London on the 14th inst. with 300 miles of deep sea cable on board, to effect the necessary repairs. The notice given by the Paris and New York Telegraph Company on the 31st December, 1886, to determine thenceforth, so far as that company was concerned, the joint purse agreements of the 24th September, 1880, and the 12th May, 1882, was submitted to eminent counsel in Paris, and, upon their advice, the associated cable companies resolved that an action should be brought by the Anglo-American Telegraph Company against the Paris and New York Telegraph Company before the Paris Tribunal of Commerce to enforce specific performance of the agreements under heavy penalties. This action is now proceeding, but as the accumulation of business before the Tribunal of Commerce is very great, it is feared that the hearing will not take place for some time. The tariff of 6d. per word has been in operation during the whole of the past half year, and has resulted in a still further increase of traffic carried by the associated companies. In consequence, however, of the Paris and New York Telegraph Company not having rendered their accounts for the period now under review, it is difficult to give a reliable estimate of the entire increase which has taken place; but inasmuch as the three companies which still work under the joint purse agreements have carried a much larger traffic than they did in the half year ending the 31st December, 1886, it is fair to assume that the total number of words carried at the sixpenny rate must have been largely augmented.

The Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 30th June, to be presented at the twentieth ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, E.C., on Friday, the 29th inst., at 2 p.m.:—

The half-year's revenue (which is subject to adjustment on settlement of the pending proceedings against the French Company), after deducting out-payments, amounted to £23,571. 15s. 4d., against £28,445. 0s. 9d.) (after similar deductions) for the corresponding period of 1886, being a difference of £4,873. 5s. 5d., against the half year under review, notwithstanding a large increase in the volume of traffic carried at the 6d. rate. This difference is entirely owing to the higher tariff in force during the first four months of 1886. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cables, amounted to £15,905. 3s. 2d., leaving a balance of £7,666. 12s 2d. as the net profit of the half year, making with £228. 18s. 8d. brought forward from the previous half year, and £4,246. 9s. 2d. transferred from the reserve fund account a total of £12,142. For the corresponding half year of 1886 the working expenses and other payments amounted to £15,866. 19s. 7d. Three quarterly interim dividends of 2s. each per share amounting to £18,213 have been declared and paid during the financial year, and a final dividend of 2s. per share is now proposed, making, with the three interim dividends 2 per cent. for the year, being a total distribution of £21,284. The interest on the reserve fund will be utilised to provide for this final dividend. A break occurred in the short section of cable on the 4th Feb. last, and was repaired on the 10th of March. On 3rd April the main section of cable was interrupted, and was repaired on 10th of same month. A further break in the short section took place on 13th April, and was repaired on 22nd April. The cost of repairing these three interruptions, including spare cable used, amounted to £5,223. 7s. 3d., which has been charged against the reserve fund as usual. The sixpenny tariff is still in force, and the volume of traffic shows a large increase.

Pursuant to the provisions of the Articles of Association, two of the Directors, viz., John Pender, Esq., and E. M. Underdown, Esq., Q.C., retire by rotation, and being eligible, offer themselves for re-election. Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the half year ended 30th June, 1887, to be presented at the thirty-second ordinary general meeting of shareholders, to be held at the offices of the Company, 61, Old Broad-street, E.C., on the 27th July, 1887, at 1 o'clock:—

From the report it will be seen that the gross receipts (including the balance brought from last account) amount to £21,292. 19s. 6d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,552. 8s. 11d., leaving a sum of £14,740. 10s. 7d. to the credit of revenue account. Of this the sum of £4,500 has been added to the reserve fund, increasing that fund to £71,000. The dividend on the preference shares will absorb £3,000, and leave £7,240. 10s. 7d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £240. 10s. 7d., being carried forward to the current half year's account. One of the harbour lengths at Cienfuegos having become worn out, a new length has been laid by Mr. Keith, the Company's engineer, to take its place. The main cables have continued throughout the half year, and are at present, in good working order. The Director who retires from the Board at this time is Mr. Joaquin de Mancha, who, being

Digitized by Google

eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor, also retires, and offers himself for re-election.

Submarine Telegraph Company.

Report of the Directors to be submitted at the meeting of the proprietors of this Company, to be held at the offices of the Company, 2, Throgmorton-avenue, London Wall, E.C., on Monday, the 25th inst., at one o'clock p.m. :—

The accounts for the six months ending 30th June, 1887, show a result which enables the Directors to add the usual proportion of the receipts to the reserve fund, and to recommend a dividend at the rate of 12 per cent. per annum, and to carry over a balance of £979. 5s. 1d. to the next account. The dividend for the corresponding period of 1886 was at the rate of 12 per cent. per annum also, and the balance carried over was £523. 5s. 7d. The average length of the messages transmitted in the half year has been 11·06 words, against 11·05 in the corresponding six months of 1886, but there has been an increase of 135,427 messages in 1887 compared with 1886. The total working expenses for the half year of 1887 show an increase of £1,005. 13s. This increase is accounted for chiefly under the heads of "Salaries and Wages," "Repair to Premises," and "Repairs and Insurance of Steamer." The number of accidents to the cables in the two half years has been about the same. All the Company's cables, as well as those worked by the Company, are in good working order. In their last report the Directors stated that the Right Hon. Robert Bourke (now Lord Connemara) had accepted the important office of Governor of the Presidency of Madras, and had in consequence resigned his seat on the Board of Directors of this Company. The Hon. John Stewart Gathorne-Hardy, M.P., had been appointed by the Board to fill the vacancy caused by Lord Connemara's resignation, subject to the approval of the proprietors. The Board recommend the election of Mr. Gathorne-Hardy as a Director of the Company.

Globe Telegraph and Trust Company (Limited).

Report of the Directors to be presented to the shareholders at the fourteenth ordinary general meeting of the Company to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 28th July, at 2 o'clock :—

The net revenue of the Company for the year, after deduction of expenses, amounts to £146,344. 17s. 2d., which, with the balance of £1,564. 6s. 2d. brought forward, makes a total of £147,919. 3s. 4d. From this amount there has been distributed the sum of £100,246. 10s. 11d. in interim dividends, leaving an available balance of £47,662. 12s. 5d. The Directors recommend payment of a final dividend for the year of 3s. per share on the preference shares, and of 2s. 3d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent. less income-tax upon the preference and 2¾ per cent. net upon the ordinary shares, carrying forward a balance of £1,439 9s. 11d. The reduction of the dividend on the ordinary shares is attributable to the continuance during the current year of the sixpenny traffic rate by the Atlantic Companies, in which this Company holds stocks and shares. Sixty of the shares of the German Norwegian Cable Company have been drawn and paid off at par, and the proceeds have been carried to credit of the capital account. The Company has acquired 400 additional shares in the French Telegraph Company, Paris to New York. By order of the High Court of Justice the preference capital of the Direct Spanish Telegraph Company was reduced from £10 per preference share to £5. In all other respects the Company's investments remain the same as in last year's accounts. In conformity with the Articles of Association, Mr. William Ford and Sir Daniel Gooch, Bart., two of the Directors, retire, but, being eligible, offer themselves for re-election. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., Barrister-at-Law, also retire at the meeting, and offer themselves for re election.

CITY NOTES, &c.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED). The Anglo-American Brush Corporation has issued the following circular to their shareholders :—

Sir,—I am instructed by the directors to inform you that of the 5,000 new shares recently offered for subscription in pursuance of the resolution passed at the last general meeting of the shareholders only 1,354 shares have as yet been taken up. The additional capital thus provided is not sufficient to meet the requirements of the corporation as a result of the acquisition of important undertakings in Austria-Hungary, and of other investments made for the purposes of further developing its business and maintaining and strengthening its position. Having regard also to the fact, already known to the shareholders, that the increasing business of the corporation has for some time past been conducted under disadvantages consequent upon inadequate working capital, the directors have decided that in the best and permanent interests of the proprietary it is desirable to make a call of £1 per share on the shares upon which only £3 per share have been paid. This call will enable the corporation to satisfactorily complete the arrangements already sanctioned by the shareholders for the necessary extension of its manufacturing and other operations, and by placing the finances on a more favourable footing facilitate the carrying out of important contracts. The directors have pleasure in stating that, considering the present depressed state of the electric light industry, the business of the corporation continues to improve in volume, though in face of keen competition and consequent fall of profits it is necessary whilst practising the most rigid economy to secure all the advantages which a command of adequate working capital affords.—I am, Sir, your obedient servant,

E. GARCKE, Secretary.

112, Belvedere-road, Lambeth, London, S.E., 16th July, 1887.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 15th July are £2,331, as compared with £2,741 in the corresponding period of 1886. The March receipts, estimated at £6,599, realised £6,708.

WOODSIDE ELECTRIC WORKS.—Mr. Joseph Davenport Finney Andrews has ceased to have any connection with the Woodside Electric Works, South Woodside-road, Glasgow, which are now under the charge of Mr. Rankin Kennedy.

NEW COMPANIES REGISTERED.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by H. Philpots, solicitor, 25, Bedford-row, W.C., with a capital of £10,000, in shares of £5 each. Object, to carry on the business of an electric lighting, motive power and supply and telephone company in all its branches. The directors shall not be more than twelve nor less than three in number, and the first shall be Mr. Henry Jasper, High-street, Chatham ; Mr. William James Mackey, High-street, New Brompton, and Mr. Charles Thomas Smith, High-street, Chatham. The general manager is Mr. Mark Parker. Qualification, the holding by each of at least 20 shares in the company. Remuneration to be determined in general meeting. The temporary registered offices of the company are at 22, High-street, Chatham.

NOTES.

BURTON-ON-TRENT.—A telephone exchange has been opened in this town by the National Telephone Company.

PORTADOWN.—We understand that the commissioners of Portadown are making inquiries about electric lighting.

A NEW WEST INDIAN CABLE.—The Spanish Government has authorised the construction of a cable between the islands of Cuba and Hayti.

"THE TELEGRAPH OF THE FUTURE."—This is the title of a work which is announced by Messrs. Trübner to appear shortly. We understand, however, that it deals with "psychic force."

SHIP LIGHTING.—The steamer "City of Aberdeen," belonging to the Aberdeen Steam Navigation Company, is being fitted with electric lighting plant by the Anglo-American Brush Company.

BRUSSELS.—Several large electric installations are now being arranged in Brussels. Amongst the most important are the lighting of the new Military Hospital, the Shaerbeck Railway Station, and at Meiselberke Station.

MARENNES.—Electric lighting continues to make steady progress amongst the towns and villages in the south-east of France, where water power is happily available. The little town of Marennes and the village of Vierza will shortly be added to the list. The contractor is M. Grejbel.

A NEW LUBRICANT FOR COMMUTATORS.—M. Bandsept informs us that he has found that Marseilles soap makes an admirable lubricant for the commutators of dynamo machines. It should be applied in very small quantity, and will be found highly efficacious in preventing the wear of the brushes.

THE TELEPHONE SUITS IN THE STATES.—According to a telegram in the *Standard* judgment has been delivered in favour of the Bell Telephone Company in its suit against the Globe Company, who were making use of Bassano and Slater's instruments. The defence was based upon the supposed priority of Meucci, the Italian inventor.

TRANS-OCEANIC TELEPHONY.—The New York daily papers want to know why their electricians do not lay a telephone cable to Europe. Mr. Barnum, we learn, "is considering the project," and thinks of ordering a special cable to transmit opera from Paris. We venture to recommend Mr. Barnum to study the writings of Oliver Heaviside.

BANK LIGHTING.—The Union Bank of London, who have for a long time past been considering the question of the electric lighting of their new premises in Princes-street, have now placed the work with Messrs. B. Verity and Sons, of King-street, Covent Garden, under the supervision of Messrs. Drake and Gorham, who are acting as engineers for the bank.

PERSONAL.—We understand that Major-General Webber, C.B., has resigned the position of managing director of the Anglo-American Brush Electric Light Corporation, and has accepted the appointment of consulting technical adviser. Mr. Emile Garcke, who for upwards of four years has been the secretary of the corporation, has been appointed manager and secretary.

A NEW INSULATING PLATE.—An insulating plate which, while very thin and light, is absolutely impermeable to moisture and to air, may be made by taking two leaves of tin-foil coated with a thin layer of gutta percha solution (dissolved in benzine or carbon di-sulphide) and placing them face to face, separated by a leaf of thin paper of close texture. This suggestion is due to M. Bandsept.

FRANCE AND OCEAN CABLES.—The scheme for promoting a cable company under the patronage of the French Government to connect the French Colonies in South America with the mother country, referred to at considerable length in our issue of February 18th, pp. 328, 334, has met with another rebuff. The Chamber of Deputies has postponed *sine die*, by a majority of 237 to 208, the first reading of a Bill to form this company.

THE PROPOSED ELECTRIC TRAMWAY AT BRAY.—The opposition to the proposed electric tramway from the terminus of the Dublin, Wicklow, and Wexford Railway Company to the strand at Bray Head having been withdrawn, the scheme has now received the sanction of the Judicial Committee of the Privy Council, and only awaits the approval of the Lord Lieutenant. We understand that the work will be placed in the hands of Messrs. Woodhouse and Rawson.

THE CARBON TRADE IN AMERICA.—We recently mentioned that the makers of electric light carbons in America had formed a combination to raise the price of carbons to remunerative rates. This move has, however, been met by the electric lighting companies of New York, who have issued a circular proposing the formation of a committee representing the whole of the arc lighting companies to consider the advisability of undertaking the manufacture of their own carbons upon a mutual basis.

SWANSEA.—The Western Counties and South Wales Telephone Company have now extended the Bristol-Cardiff trunk line as far as Swansea, a total length of 116½ miles. The line will shortly be carried on to Llanelly, 12 miles further. At present only a single wire has been completed between Swansea and Cardiff, and that portion of the line is worked through an earth return. In another fortnight, however, it is anticipated that the metallic circuit will be complete throughout. In the meantime conversation between Bristol and Swansea is even now carried on without difficulty.

THE TAMINE ACCUMULATOR.—M. Tamine, of Brussels, has devised an accumulator of the Planté type, in which the liquid consists of a saturated solution of sulphate of zinc, to which is added 50 per cent. of sulphuric acid, 5 per cent. of sulphate of ammonia and 5 per cent. of sulphate of mercury. In making up the cell it is stated that the ingredients should be poured in in the reverse order to that here enumerated. The E.M.F. of the cell is given as 2·3 volts. The addition of sulphates of mercury and ammonia is said to prevent the formation of sulphate of lead on open circuit. The solution appears to be practically identical with that employed in M. Mezerolle's cell.

MALTON.—The Malton proposals have resulted pretty much in the way which might have been anticipated after reading the details which we gave in our last issue; that is to say, out of twenty-four firms who examined the specification of the borough surveyor not a single one proceeded to tender. This result is far more satisfactory than the recurrence of any catch-penny offers such as have too often been made. The Gas Company offered to provide the stipulated number of burners, to consume 5ft. of gas per hour, and to burn 1,700 hours per annum, at a yearly rate of £2. 3s. 6d. per lamp. This offer led to a heated discussion, and the matter still remains unsettled.

PARIS.—It is reported that the Edison Company has applied for powers to open a central lighting station in the neighbourhood of the Théâtre Français. MM. Davy Lepage and Cie. are also negotiating for the establishment of a station in the Boulevard de Strasbourg.—The Paris General Telephone Co. has contracted for supplying the Buenos Ayres Telephone Co.,

Digitized by Google

just formed, with all the requisite instruments, material, and plant for the establishment of the telephone system in the Argentine capital. The Paris Company has also received an order for cables from the Buenos Ayres Municipality, the latter having decided to make an experiment in lighting the city by electricity.

WHAT IS A "SELF-REGULATING" DYNAMO?—A correspondent is anxious to be informed "whether a patent compound-wound self-regulating dynamo-electric machine, in which the brushes are shifted by hand for variable loads, and an adjustable resistance is placed in circuit with the shunt coils, may be considered to possess any marked superiority over machines in which these features are absent?" After carefully considering this curious point raised by our correspondent we are inclined to reply to his question in the negative. But as we are aware that other views are held by (presumably) high authorities, we cannot ask him to attach too much importance to an editorial opinion.

MEETING OF THE INSTITUTE OF MECHANICAL ENGINEERS.—The summer meeting of the Institute of Mechanical Engineers will be held in Edinburgh, on Tuesday morning, August 2, and Wednesday morning, August 3, in the University. The chair will be taken at half-past nine o'clock by the President, Mr. Edward H. Carbutt, in the Natural History Lecture Theatre. The following amongst other papers have been offered for reading and discussion:—"A Description of the Electric Light on the Isle of May," by Mr. David A. Stevenson, of Edinburgh; "On Electro-Magnetic Machine Tools," by Mr. Frederick John Rowan, of Glasgow; "On the Position and Prospects of Electricity as Applied to Engineering," by Mr. William Giepel, of Edinburgh.

SECONDARY BATTERIES IN BELGIUM.—We understand that a syndicate has been formed at Brussels with a view to the acquisition of the whole of the Belgian patents (of any practical importance) relating to secondary batteries. It is believed that arrangements will be concluded with most of the present holders on the basis of an average royalty of two centimes per kilogramme of plates manufactured. The principal object in view is to unite all the valuable features at present distributed amongst numerous patents so as to obtain the best possible form of cell free from all patent troubles and trials. This is a sensible idea, and we shall hope to hear that the negotiations have been carried to a successful issue in time for the International Exhibition which is to take place next year at Brussels.

THE BRUCE ELECTRICAL WAR BALLOON.—On Monday evening last Mr. E. S. Bruce exhibited his electric war balloon at the Kensington Town Hall. The apparatus is intended for aerial signalling. The balloon is of varnished cambric, with a capacity of 2,000 cubic feet. The interior contains a frame, in the form of a ladder, suspended in its centre, holding six incandescent lamps of the Edison and Swan type, of 25 volts, the current being conveyed to the frame by a flexible double cable. The lamps are controlled from a switch board, the contacts being of carbon instead of platinum, and the balloon is held captive by a line of Italian hemp capable of bearing a breaking strain of 25 tons. The apparatus is worked with an E.P.S. battery of 25 cells. We understand that the trials which have been made at Chatham have convinced the military authorities of the utility of the idea. The apparatus exhibited has been made for the Belgian Government.

THE PARIS, 1889, EXHIBITION: PROPOSED NOVEL ELECTRIC RAILWAY.—In a paper read by M. Eugène Hénard before the French Society of Architects, it has been proposed to lay down a "continuous" electric railway or "carrying platform" around the whole of the grounds of the Paris Exhibition. The idea is to lay the rails in a trench of such a depth that an ordinary flat-topped railway waggon just reaches the surface of the ground; the whole circle would then be filled with a train of such waggons coupled close together and provided with a continuous floor. This train is to be driven at a walking pace by a number of electric motors placed at intervals upon or underneath the waggons. Passengers can thus step on or off at any point, and no fares would be charged except for seats. The working of the line would be controlled from signal boxes placed at suitable distances, from each of which the train may be stopped at any moment by opening one of the main leads. The idea strikes us as a rather good one, and there should be no difficulty in carrying it out with entire success, and with great convenience to visitors.

SEILER'S HOTEL ANNUNCIATOR SYSTEM.—In order to reduce the number of electro-magnetic drops which are required in fitting a large building with electric bells and annunciators, Mr. P. Seiler (of San Francisco) has brought out a system whose merit consists chiefly in the use of a limited number of annunciators to indicate a much larger number of rooms. This is carried out by placing the numbers of the rooms on fixed tablets arranged in a square or rectangular form, and having two rows of annunciators which run along the top and down one side of the board, so that by the fall of any two of the annunciator drops a particular number is indicated. The arrangement for actuating the drops is ingenious. When a call is first received an annunciator in the horizontal row only is seen to fall. The signal is then acknowledged by the attendant, who presses the key which is found at the bottom of the vertical row of numbers indicated by the drop. The pressing of this key causes the second drop in the vertical row of annunciators to fall, indicating the number of the room, and at the same time giving an acknowledgement of the signal.

METHOD OF PREVENTING THE BLACKENING OF INCANDESCENT LAMPS.—Mr. Ed. P. Thompson has found that the blackening of the glass of incandescent lamps is chiefly due to the carbon particles which are driven off on first closing the circuit when the filament obtains a static charge. In order to avoid this Mr. Thompson has made lamps in which the filament surrounds a loop or stem of copper wire, which passes through the stem of the lamp and is connected to earth; the wire being also provided with several points which project towards the filament. The result is that when the static charge is received the carbon molecules tend to be projected upon the wire, and the blackening of the glass is prevented. Mr. Thompson's theoretical explanation of the effect is certainly sufficiently plausible to merit consideration, but it appears to us that if this view were correct it would follow that incandescent lamps supplied with alternating currents should blacken much more rapidly than with continuous currents, and their life should be much shorter. We have not learnt that such a result has ever been observed, and it would almost appear that this objection is fatal to the static charge theory.

HOW TO FORM A PRIMARY BATTERY COMPANY.—The following instructions upon this interesting and important subject are taken from an American technical journal. The business appears, however, to be tolerably well understood in certain quarters on this side the Atlantic:—"Organise under the laws of the State of Maine; 10,000 shares of stock, par value, $100 per share. Offer to let in your friends on the ground floor at $1 per share. Print some circulars, setting forth the millions [not] made in primary batteries, in times

Digitized by Google

gone by; explain indefinitely that a new discovery has been made of an [old] chemical by the aid of which current can be produced for domestic incandescent lighting. There are as gullible investors as ever were caught, and they will bite. Delays are convenient—carbons not ready; cups too porous. Keep this up as long as possible, and then get some batteries, and run one or two incandescent lights far above their candle power. Do not let them burn but a few moments at a time, and a 5 candle-power run up to 25 candle-power will last some days. Comment on the whiteness and steadiness of the light. When people apply for batteries convince them of their folly, and induce them to purchase stock. When the enthusiasm is at its height sell the stock, and be conveniently called to some other section of the world for a year. On returning repeat the same operation."

VULCABESTON.—Vulcabeston is the name of a new material which professes to combine all the valuable qualities of asbestos and india rubber. It is described as forming a substance of the toughness of horn, although it can be made of any degree of flexibility. It is a non-conductor of electricity, and stands the severest test of acids, steam, gases, &c. One of the most important uses of the new material is as a moulded piston rod packing ring, made to fit any sized rod or stuffing box, and to be sprung in place with a slight pressure, one or more rings being used as desired, and forming a perfectly tight steam joint. These rings do not wear the rod, and they are self-lubricating. The first set made of these rings has been in use over eleven months, in a Hartfort, Conn., manufactory, on an engine run at 280 strokes per minute, and is still in perfect order. Vulcanised asbestos piston rod packing in the form of flexible rope, of all sizes, will not shrink or blow out, and is especially adapted for use on locomotives and ocean steamers, and in other places where loss of time in repacking is of the greatest consequence, and where the use of ordinary steam packings would consequently be entirely inadmissible. And it is claimed that in consequence of its great strength and durability it can be used wherever metallic packings have heretofore been necessary. If all this is true the new material may be expected to do good service in connection with engines for central station electric lighting.

GALLANT CONDUCT OF TWO ELECTRICIANS.—We have pleasure in recording two very gallant rescues from drowning which took place last week at Waterford, and of which Messrs. Pope and Bate, of the firm of Laing, Wharton and Down, were the heroes. These gentlemen are at present engaged in the erection of a Thomson-Houston plant for lighting the City of Waterford, and were bathing in the bay on Thursday morning, although the water was somewhat rough. On the left hand side of the bay a strong under-current exists, and after being in the water some time Mr. Bate observed a man in an unconscious condition and drifting out to sea in the current. Shouting to his colleague, they both dashed to the rescue. The drowning man was first reached by Mr. Pope, who, after an exhausting struggle for ten minutes in the heavy seas, brought him safely to land. Mr. Pope found himself completely done up and unable to stand, but while being attended to by Mr. Bate, cries were again heard from the sea, and a priest, Father Dooley, was discovered vainly endeavouring to support another half-drowned individual whom he had gone to rescue. Mr. Bate seized a life-buoy, and again plunging into the water, succeeded, with the aid of a bystander named Phelan, in bringing both men safely to shore. The individual saved by Mr. Pope was a medical student named Keogh, and in the second case Mr. O'Farrel, a ship-broker, was concerned. We are glad to hear from Messrs. Laing, Wharton, and Down that they are taking steps to bring the matter before the Royal Humane Society.

THE PARTNERSHIP BETWEEN GAS AND ELECTRICITY IN AMERICA.—The annual report of the American Electric Manufacturing Company contains the following reference to their alliance with the gas interest:—"The past year has demonstrated the soundness of the opinion long entertained and persistently advanced by the officers of this company, that the gas and electric lighting interests of the country should co-operate instead of antagonising each other. Gas lighting companies have finally come to recognise the fact that their interests are best subserved by the combination of the two illuminants for local lighting purposes under one management, and that it is far better for them to add electric lighting apparatus to their present plants, and thus prepare themselves to meet the entire demand for illumination in their respective localities than to permit others to introduce the newer and more brilliant illuminant as a rival to gas. They have found that such a combination is not only practicable and profitable, but that the adoption of electric lighting by gas companies practically excludes competitors because of the superior economy with which such companies can operate electric lights in connection with their established gas business. Other electric lighting companies have at last perceived that the combination is inevitable, and are tardily endeavouring to obtain the adoption of their respective systems. But the American Company is pretty generally recognised as the pioneer in this direction, and will naturally enjoy the largest share of the patronage of the gas companies, especially in view of the superiority of its apparatus. Recognising the great importance of the company's future dealings with this extensive and important industry, the trustees established a special gas department of the company's business, and have placed in special charge thereof one of the most experienced, successful, and widely known gas engineers in the country."

ELECTRIC TRACTION.—Considerable light is shed upon the causes of the very partial success of electric traction on the Brussels tram lines when we learn that an attempt was made to use a dynamo of old-fashioned type as a motor. Upon the long and steep gradients of the Brussels line the torque upon the armatures must be very great indeed, and it was little short of folly to expect an armature built for a totally different purpose to withstand the strain. Whatever points of divergence have yet to be settled in the theory of dynamos and motors, it is yet fully understood—or at any rate it is high time that it should be—that a motor which is geared in a positive manner, and is liable to be started under a heavy load, must be designed, both mechanically and electrically, on the basis of an output far exceeding its normal rate of working. An old-fashioned dynamo is simply useless for work of this description. The Brussels Company having now fully convinced themselves upon this point, we understand that it has been decided to employ motors of English make, and M. Julien was recently in this country making inquiries. We are pleased to learn that the Julien cells continue to give satisfaction. Each car, weighing with its load of passengers 16,500lb., carries in addition a weight of 3,300lb. of accumulators. This ratio of weight of battery to total weight is slightly lower than that obtained by the Electric Traction Syndicate (as described in another column), but this in part arises from the fact already alluded to, that the motor is too light for its work. But as we are not aware of the total capacity of the cells in the former case, the comparison is not of much value. The battery consists of 120 cells, which are coupled to a switch, so as to

Digitized by Google

like operations that could be conceived; but I do not think we should give in to the outside public, and that while we increase the facilities for business ws should lower the profit we are entitled to receive. If our property is so permanent in its character, power, and influence, it does seem proper that our shareholders should share in its increased prosperity, and that the increased profits should not be as a rule surrendered to others unless overwhelming force compels it.

Mr. HUSBAND: Before you answer I want to ask you a question with respect to the new line that is to bs laid to Gibraltar. I was going to ask first of all with what money the line is to be laid, whether it is to be laid out of the reserve fund, and I also wish to ask how much it will cost? In relation to the remarks made by the gentleman who has just sat down, in comparing the dividend of 5½ per cent. with 6 per cent. that we had once, one reason why it seems to me reasonable to expect that we should at least keep up the dividend is the fact that we have so large a reserve fund. I see that we have in money £564,000 of reserve capital; but in addition to that I find by our accounts—this is on page 6 of the report—there is a duplicate cable in the Red Sea and Indian Ocean representing £100,000, there is a triplicate Red Sea and other cables representing £300,000, and these, so far as I can see, are made out of the £448,000, which is itself reserve fund, and which is therefore costing no interest, either as debenture or as dividend. It seems, assisted as you are by a million of money and the money's worth in your reserve fund, that to keep up the dividend at 6 per cent. would not entitle the Directors to the credit of having done anything superlatively meritorious. I have no doubt that you will answer my first question, at any rate, as to what is to pay for the new line to Gibraltar, and also what the amount is that it is to cost; and perhaps you would also go the length of saying what dividend you expect that line to make when it is laid.

Mr. FOWLER: There is one question I should like to ask arising out of a remark made as to the issue of their capital. I understood you to say the capital would not be materially increased, which means that it will be increased. I would venture to ask whether that additional capital will be offered in the first instance to the existing shareholders *pro rata* according to their holdings. I presume the capital will be partly ordinary and partly preference, as the Directors may think convenient. I only wish to know if the existing shareholders will be offered their proportion of the capital first.

Mr. BAINES: I was going to ask a question—it is perhaps important to the Company's interests—whether in the event of your negotiations with the French Government as to renewing your concession with them failing—whether any loss of time will be made in transmitting messages by the altered route?

The CHAIRMAN: First I have to thank Mr. Newton for bringing the question of the security of our new debentures before the shareholders, and I think he will be pleased with the reply of our solicitor. You are getting better security for your 4 per cent. than you had for your 5 per cent. In regard to Mr. Griffith's remarks, it is always very pleasant to keep up the full extent of your dividend, but you must remember when we established the bonus principle I stated to the shareholders that we would consider the 5 per cent. as our dividend, and that when we could pay bonuses we would do so—that the bonus was not to be looked upon as a permanent thing, but that it should be of a fluctuating character, and be 1 per cent. for the year, or 2 per cent., or ½ per cent., according to circumstances. I merely mention that to show you that the bonus is distinct from the dividend. The reason that we did not pay ½ per cent. for the first half year was that at Berlin an alteration took place in the land line systems by which the European Governments, with their long purses behind them, came to an arrangement which obliged us to alter our tariff. We were forced, therefore, to reduce our rates, and that amounted to £40,000 a year. That wiped away for the time our bonus, and now, with time going on, we are to a certain extent recouping our lost traffic. I hope next half-year we may again pay our ½ per cent., and therefore take up the position of paying our bonus, but still as distinct from paying our dividend. There will be great fluctuations in telegraph property. There must be. It is an uncertain property, I say, still; but at the same time we know in our shallow water where we can pick up a cable, and we are doing it every day. Demands, however, may come upon us at any time, and we must keep ahead of the wants of the Government and of the country, and in keeping ahead of these wants we have received great and important consideration from the Government. For instance, we had the exclusive right for a very considerable number of years of landing cables in Egypt. That is an advantage to this Company which is worth almost untold money, particularly when you look to the fact of the competition in connection with the Atlantic cables at the present moment, for those companies are paying practically no dividend at all. It has been our object so to make our arrangements as to regulate our traffic, and maintain a respectable dividend, and a permanent dividend, and that we have done up to the present time. I would say to Mr. Griffith that we cannot stand still. That would be impossible. If we were to stand still we must go back. There is an increasing demand one way or another, and we must, as far as possible, meet that demand, and be ahead of it. Replying to Mr. Husband, the Chairman explained how the Company proposed to pay for the new cable without materially increasing the capital account. I am looking forward to a very large increase in the traffic. I think it must come, looking to the arrangements likely to be made with Australia for lower rates. Therefore, with our new cable down we are quite independent of France. Still, if France is reasonable—they do not show a very good disposition to meet us up to this moment—yet if next year, when our concession expires with the French Government, they say that we shall hold the cable, it will be an advantage, looking forward to this expected increase of traffic. This will give us an alternative line. I think these remarks will satisfy you that we are reducing the expenses of the new cable to a minimum. We are going to pay towards that cable what we pay to the French Government and other companies at the present moment, and I hope that that will be satisfactory to you. Mr. Fowler asked if we are prepared to give the shareholders *pro rata* the option to subscribe to the capital we shall require for the new cable. I assure you we are going to finance that so as practically to add nothing to the capital. I am as far as possible against adding to the capital, but I think you should be more satisfied with a permanent 5 per cent. and an occasional bonus now and then than leaving our system to drift and competition to arise, and permitting your dividends to be reduced to a mere nominal amount. It is our business to do our work so well that neither Governments nor the outside public will try to tread upon our ground. I was asked if there would be any delay in transmitting the messages. Our arrangement with France goes up to next year; but France may be in a blaze to-morrow for what I know. Judging from what we read in *The Times* the state of things looks very alarming. At all events, to show you how much alive we are to the position—though we do not talk about it, as we do not want to add to scares—the ship is now at Porthcurnow with a large amount of cable on board, and, I believe, could lay the cable in a month.

Mr. NEWTON: Will you compete with your new cable with the Direct Spanish? We are all one company.

The CHAIRMAN: We do not lose sight of that. We are even anxious now to come to an arrangement with Spain. Our negotiations, indeed, are so far advanced that we shall have one of these days an alternative line from Bilbao to Barcelona connected with our system, and from Barcelona we shall connect with our main system at Gibraltar at very small expense. That would give us another line. "Sufficient for the day," however. We have it all in view, and are losing sight of nothing, our desire being to place our Company, in the event of war, in such a position that it will be able to meet, not only public requirements but Government requirements as well. The resolution has been moved and seconded, and with these few remarks I now put it. Those in favour of the motion hold up their hands. To the contrary. Carried unanimously. That closes the meeting.

Major LESLIE: Will you let me move a vote of thanks to our Chairman? I think we must be all very much pleased and gratified at hearing such an eloquent and pleasing statement on our position, and the success we have achieved in attaining to such a fair dividend. After the loss that was caused to us through the action of the Powers of Europe, I think what has been done for us deserves our best thanks.

Mr. GRIFFITH: I shall be happy to second the motion. I am sure that the shareholders will support the Directors whenever any improper action is brought against us by the Governments, with their long purses. We are indebted to Mr. Pender for the kind way in which he has answered our questions. We are indebted to him also for the great experience and skill which he has displayed in the management of the Company, and I certainly cordially support the proposal that we tender a vote of thanks to Mr. Pender and his colleagues.

Major LESLIE put the motion, and it was carried unanimously.

The CHAIRMAN: Gentlemen, it is the greatest possible pleasure to my colleagues and myself to have an expression of the renewed confidence of the shareholders. You may rest assured that the experience we have gathered over many years, as well as the position we have attained, has arisen in a great measure from the confidence which the shareholders have shown in us from time to time at these half-yearly meetings. We have had to-day one of our most severe critics with us. We have a great deal more experience here to-day than we had a few years ago. We have been always glad to have hints given to us, and we have never lost sight of them, and where we have thought they were right and proper we have taken advantage of them. The result is that the position which this Company occupies to-day is second to that of no other telegraph system in the world, and it will continue to receive our most careful attention. We find those who came at first to be severe on us now come to compliment us. That is our reward. We are much obliged to you for your attendance here to-day.

The proceedings then terminated.

The Telegraph Construction and Maintenance Company (Limited).

The half-yearly general meeting of this Company was held on Tuesday, at the offices, 38, Old Broad-street, E.C., Sir George Elliot, M.P., in the chair.

Mr. WILLIAM SHUTER (the Manager) having read the notice convening the meeting,

The CHAIRMAN said: At the request of my colleagues I occupy the chair owing to the absence of our worthy and highly esteemed chairman, Sir Daniel Gooch, who has had a slight accident. I am very thankful and glad to say that I believe it is only slight, but sufficient, I believe, to confine him for a few days. We should all very deeply regret the loss of the useful attention of so valuable a colleague as our Chairman. Well, now, as to the business before the meeting, this is really practically so insignificant that were it not for the purpose of the shareholders keeping touch as it were with what is going on from time to time these half-yearly meetings, which were instituted some years ago, might be dispensed with. At the same time we are very glad to see all of you here, and I will just point out that which will appear to be the only business with which we have to make you acquainted. It is the work done for the half year under contract. We have connected the Italian ports in the Red Sea with Aden, using 359 miles of cable—that is one thing done. The next thing is we have repaired the German Union Company's cable in the North Sea. With regard to the more important work which we are now engaged upon, the "Scotia," which is one of our excellent ships, the property of the Company (we have not to charter vessels now) left England on the 11th inst. with 1,300 miles of cable on board to con-

Digitized by Google

nect the Land's End with Lisbon and Gibraltar, and she is now carrying out that work. Submarine telegraph companies find it almost necessary to duplicate their lines, and wherever there is one cable another in course of time is required. That is very much what constitutes the life, as it were, of this Telegraph Construction Company, to go on developing and replacing, and I hope it will continue so for many years. I do not know that I have more to report to you than merely mention these facts. We are hopeful that we shall continue to satisfy the shareholders; at the same time we have a very great staff, and we are desirous to be employed, and we are not without prospect that that may be continued to us. I believe there is no resolution to submit; it is merely that we come to see you, and so long as we can go on paying our dividends I am sure we will always be quite certain to have your confidence, and that is what the business is, not to have too much curiosity or prying into what is being done, but to be satisfied with a good dividend.

A SHAREHOLDER: I am sure I am only expressing the regret of all the shareholders at the intelligence we have from you (and which we knew for ourselves) as to the accident which has befallen the worthy Chairman. You may recollect at the last half-yearly meeting I asked some questions of the Chairman with regard to the electric light, and the Chairman very properly, if I may say so, declined to say anything on the ground that an action was then pending, and which was shortly to be brought to a conclusion. That action has now come to an end favourably to this Company, I believe, and I think the shareholders would be glad to know, Sir, from you, if you can tell them, in the absence of the Chairman, whether you propose to take any steps in developing the electric light through the medium of this Company?

The CHAIRMAN: The hon. shareholder has asked a question which I think is very pertinent; the litigation has been successful. It was resisted by the Great Western Railway; it is not our litigation, we were not subject to its costs, and it has been terminated favourably. We have before us there, what was contemplated, a great example of what can be done, and I believe it is the subject of serious consideration with the Directors what use and how far the experiment may be utilised in connection with the development of the business of this Company. I hope that answer will be satisfactory to everyone. We hope it may become useful, and that we may be able to do any work in connection with electricity, so far as we are concerned with the materials we have, that may be required. I do not know that there is anything more.

Mr. WILLIAM SHUTER: If you will allow me I will read this notice relative to the Second Bonus Trust:—"The Second Bonus Trust (which formed part of the dividend paid to shareholders on the Company's register in February, 1885), the trustees having realised the balance of shares constituting the trust, the above certificates, with Coupon No. 24 attached, are now being paid off at the rate of £1. 7s. per £5 nominal value (£2. 10s. being paid off in August, 1881). Capital unclaimed at Messrs. Barclay's Bank:—First distribution about £1,000, Second and Final £11,000, Coupons £500." That will go forward in the report, and I hope the claims will come forward.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

A meeting of the shareholders in this Company was held on Tuesday, at the Cannon-street Hotel, Mr. S. W. Silver presiding.

The SECRETARY (Mr. W. J. Tyler) having read the notice convening the meeting,

The CHAIRMAN said: The shareholders will be aware that the books of the Company are not made up until the close of the year. They will not be surprised to hear from me that the same keen competition that has already been alluded to is still met with by the Company as a trading concern, and I need scarcely remind you that that state of things requires on the part of the managers and others the greatest possible attention to effect sales, which I hope, when the books are made up, will be found to justify the motion which I now beg to propose, namely, "That an interim dividend of 5 per cent., or 10s. a share, free of income-tax, be payable on and after the 20th inst."

Mr. NEIL BANNATYNE seconded the motion, which was carried unanimously, and a vote of thanks to the Chairman and Directors having been cordially passed, the proceedings terminated.

Anglo-American Telegraph Company (Limited).

Report of the Directors to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, 27th inst., at half-past one o'clock:—

The total receipts from the 1st January to the 30th June, 1887, are estimated at £100,534. 9s. 3d. This amount, however, is subject to revision, dependent upon the result of the law-suit now pending between this Company (on behalf of the associated Atlantic cable companies) and the Paris and New York Telegraph Company. The traffic receipts show a decrease as compared with the corresponding period of last year of £16,492 consequent upon competition, a reduced tariff, and the fact that from 1st January to 4th May, 1886, the 1s. 8d. rate was in force. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £47,211. 2s. 7d. One quarterly interim dividend of 5s. per cent. on the ordinary stock, and of 10s. per cent. on the preferred stock, was paid on the 1st May, 1887, absorbing £17,500, and second quarterly dividends of similar amounts will be distributed on the 30th July, 1887, leaving an estimated balance of £18,323. 6s. 8d. to be carried forward to the next account.

The Company's repairing ss. "Minia" has been engaged during the past half-year in the repair of the 1873 cable off Valentia, Ireland, and the St. Pierre Duxbury cable off Seal Island, Nova Scotia. She has also executed three repairs for the Direct U.S. Cable Company and two for the Western Union Telegraph Company, the remuneration for which will be found in the revenue account. The Company's system of cables and land wires is in good working order, with the exception of the Brest St. Pierre and St. Pierre Duxbury cables, the former of which was broken in deep water at a distance of 600 miles from Saint Pierre on the 9th November, 1886, and the latter in shallow water at a distance of 380 miles from Duxbury on the 15th June, 1887. The Company's ss. "Minia" left London on the 14th inst. with 300 miles of deep sea cable on board, to effect the necessary repairs. The notice given by the Paris and New York Telegraph Company on the 31st December, 1886, to determine thenceforth, so far as that company was concerned, the joint purse agreements of the 24th September, 1880, and the 12th May, 1882, was submitted to eminent counsel in Paris, and, upon their advice, the associated cable companies resolved that an action should be brought by the Anglo-American Telegraph Company against the Paris and New York Telegraph Company before the Paris Tribunal of Commerce to enforce specific performance of the agreements under heavy penalties. This action is now proceeding, but as the accumulation of business before the Tribunal of Commerce is very great, it is feared that the hearing will not take place for some time. The tariff of 6d. per word has been in operation during the whole of the past half year, and has resulted in a still further increase of traffic carried by the associated companies. In consequence, however, of the Paris and New York Telegraph Company not having rendered their accounts for the period now under review, it is difficult to give a reliable estimate of the entire increase which has taken place; but inasmuch as the three companies which still work under the joint purse agreements have carried a much larger traffic than they did in the half year ending the 31st December, 1886, it is fair to assume that the total number of words carried at the sixpenny rate must have been largely augmented.

The Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 30th June, to be presented at the twentieth ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, E.C., on Friday, the 29th inst., at 2 p.m.:—

The half-year's revenue (which is subject to adjustment on settlement of the pending proceedings against the French Company), after deducting out-payments, amounted to £23,571. 15s. 4d., against £28,445. 0s. 9d.) (after similar deductions) for the corresponding period of 1886, being a difference of £4,873. 5s. 5d., against the half year under review, notwithstanding a large increase in the volume of traffic carried at the 6d. rate. This difference is entirely owing to the higher tariff in force during the first four months of 1886. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cables, amounted to £15,905. 3s. 2d., leaving a balance of £7,666. 12s 2d. as the net profit of the half year, making with £228. 18s. 8d. brought forward from the previous half year, and £4,246. 9s. 2d. transferred from the reserve fund account a total of £12,142. For the corresponding half year of 1886 the working expenses and other payments amounted to £15,866. 19s. 7d. Three quarterly interim dividends of 2s. each per share amounting to £18,213 have been declared and paid during the financial year, and a final dividend of 2s. per share is now proposed, making, with the three interim dividends 2 per cent. for the year, being a total distribution of £21,284. The interest on the reserve fund will be utilised to provide for this final dividend. A break occurred in the short section of cable on the 4th Feb. last, and was repaired on the 10th of March. On 3rd April the main section of cable was interrupted, and was repaired on 10th of same month. A further break in the short section took place on 13th April, and was repaired on 22nd April. The cost of repairing these three interruptions, including spare cable used, amounted to £5,223. 7s. 3d., which has been charged against the reserve fund as usual. The sixpenny tariff is still in force, and the volume of traffic shows a large increase.

Pursuant to the provisions of the Articles of Association, two of the Directors, viz., John Pender, Esq., and E. M. Underdown, Esq., Q.C., retire by rotation, and being eligible, offer themselves for re-election. Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the half year ended 30th June, 1887, to be presented at the thirty-second ordinary general meeting of shareholders, to be held at the offices of the Company, 61, Old Broad-street, E.C., on the 27th July, 1887, at 1 o'clock:—

From the report it will be seen that the gross receipts (including the balance brought from last account) amount to £21,292. 19s. 6d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,552. 8s. 11d., leaving a sum of £14,740. 10s. 7d. to the credit of revenue account. Of this the sum of £4,500 has been added to the reserve fund, increasing that fund to £71,000. The dividend on the preference shares will absorb £3,000, and leave £7,240. 10s. 7d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £240. 10s. 7d., being carried forward to the current half year's account. One of the harbour lengths at Cienfuegos having become worn out, a new length has been laid by Mr. Keith, the Company's engineer, to take its place. The main cables have continued throughout the half year, and are at present, in good working order. The Director who retires from the Board at this time is Mr. Joaquin de Mancha, who, being

Digitized by Google

eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor, also retires, and offers himself for re-election.

Submarine Telegraph Company.

Report of the Directors to be submitted at the meeting of the proprietors of this Company, to be held at the offices of the Company, 2, Throgmorton-avenue, London Wall, E.C., on Monday, the 25th inst., at one o'clock p.m. :—

The accounts for the six months ending 30th June, 1887, show a result which enables the Directors to add the usual proportion of the receipts to the reserve fund, and to recommend a dividend at the rate of 12 per cent. per annum, and to carry over a balance of £979. 5s. 1d. to the next account. The dividend for the corresponding period of 1886 was at the rate of 12 per cent. per annum also, and the balance carried over was £523. 5s. 7d. The average length of the messages transmitted in the half year has been 11·06 words, against 11·05 in the corresponding six months of 1886, but there has been an increase of 135,427 messages in 1887 compared with 1886. The total working expenses for the half year of 1887 show an increase of £1,005. 13s. This increase is accounted for chiefly under the heads of "Salaries and Wages," "Repair to Premises," and "Repairs and Insurance of Steamer." The number of accidents to the cables in the two half years has been about the same. All the Company's cables, as well as those worked by the Company, are in good working order. In their last report the Directors stated that the Right Hon. Robert Bourke (now Lord Connemara) had accepted the important office of Governor of the Presidency of Madras, and had in consequence resigned his seat on the Board of Directors of this Company. The Hon. John Stewart Gathorne-Hardy, M.P., had been appointed by the Board to fill the vacancy caused by Lord Connemara's resignation, subject to the approval of the proprietors. The Board recommend the election of Mr. Gathorne-Hardy as a Director of the Company.

Globe Telegraph and Trust Company (Limited).

Report of the Directors to be presented to the shareholders at the fourteenth ordinary general meeting of the Company to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 28th July, at 2 o'clock :—

The net revenue of the Company for the year, after deduction of expenses, amounts to £146,344. 17s. 2d., which, with the balance of £1,564. 6s. 2d. brought forward, makes a total of £147,919. 3s. 4d. From this amount there has been distributed the sum of £100,246. 10s. 11d. in interim dividends, leaving an available balance of £47,662. 12s. 5d. The Directors recommend payment of a final dividend for the year of 3s. per share on the preference shares, and of 2s. 3d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent. less income-tax upon the preference and 2¾ per cent. net upon the ordinary shares, carrying forward a balance of £1,439 9s. 11d. The reduction of the dividend on the ordinary shares is attributable to the continuance during the current year of the sixpenny traffic rate by the Atlantic Companies, in which this Company holds stocks and shares. Sixty of the shares of the German Norwegian Cable Company have been drawn and paid off at par, and the proceeds have been carried to credit of the capital account. The Company has acquired 400 additional shares in the French Telegraph Company, Paris to New York. By order of the High Court of Justice the preference capital of the Direct Spanish Telegraph Company was reduced from £10 per preference share to £5. In all other respects the Company's investments remain the same as in last year's accounts. In conformity with the Articles of Association, Mr. William Ford and Sir Daniel Gooch, Bart., two of the Directors, retire, but, being eligible, offer themselves for re-election. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., Barrister-at-Law, also retire at the meeting, and offer themselves for re election.

CITY NOTES, &c.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED). The Anglo-American Brush Corporation has issued the following circular to their shareholders :—

Sir,—I am instructed by the directors to inform you that of the 5,000 new shares recently offered for subscription in pursuance of the resolution passed at the last general meeting of the shareholders only 1,354 shares have as yet been taken up. The additional capital thus provided is not sufficient to meet the requirements of the corporation as a result of the acquisition of important undertakings in Austria-Hungary, and of other investments made for the purposes of further developing its business and maintaining and strengthening its position. Having regard also to the fact, already known to the shareholders, that the increasing business of the corporation has for some time past been conducted under disadvantages consequent upon inadequate working capital, the directors have decided that in the best and permanent interests of the proprietary it is desirable to make a call of £1 per share on the shares upon which only £3 per share have been paid. This call will enable the corporation to satisfactorily complete the arrangements already sanctioned by the shareholders for the necessary extension of its manufacturing and other operations, and by placing the finances on a more favourable footing facilitate the carrying out of important contracts. The directors have pleasure in stating that, considering the present depressed state of the electric light industry, the business of the corporation continues to improve in volume, though in face of keen competition and consequent fall of profits it is necessary whilst practising the most rigid economy to secure all the advantages which a command of adequate working capital affords.—I am, Sir, your obedient servant,

E. GARCKE, Secretary.

112, Belvedere-road, Lambeth, London, S.E., 16th July, 1887.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 15th July are £2,331, as compared with £2,741 in the corresponding period of 1886. The March receipts, estimated at £6,599, realised £6,708.

WOODSIDE ELECTRIC WORKS.—Mr. Joseph Davenport Finney Andrews has ceased to have any connection with the Woodside Electric Works, South Woodside-road, Glasgow, which are now under the charge of Mr. Rankin Kennedy.

NEW COMPANIES REGISTERED.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by H. Philpots, solicitor, 25, Bedford-row, W.C., with a capital of £10,000, in shares of £5 each. Object, to carry on the business of an electric lighting, motive power and supply and telephone company in all its branches. The directors shall not be more than twelve nor less than three in number, and the first shall be Mr. Henry Jasper, High-street, Chatham ; Mr. William James Mackey, High-street, New Brompton, and Mr. Charles Thomas Smith, High-street, Chatham. The general manager is Mr. Mark Parker. Qualification, the holding by each of at least 20 shares in the company. Remuneration to be determined in general meeting. The temporary registered offices of the company are at 22, High-street, Chatham.

NOTES.

BURTON-ON-TRENT.—A telephone exchange has been opened in this town by the National Telephone Company.

PORTADOWN.—We understand that the commissioners of Portadown are making inquiries about electric lighting.

A NEW WEST INDIAN CABLE.—The Spanish Government has authorised the construction of a cable between the islands of Cuba and Hayti.

"THE TELEGRAPH OF THE FUTURE."—This is the title of a work which is announced by Messrs. Trübner to appear shortly. We understand, however, that it deals with "psychic force."

SHIP LIGHTING.—The steamer "City of Aberdeen," belonging to the Aberdeen Steam Navigation Company, is being fitted with electric lighting plant by the Anglo-American Brush Company.

BRUSSELS.—Several large electric installations are now being arranged in Brussels. Amongst the most important are the lighting of the new Military Hospital, the Shaerbeck Railway Station, and at Meiselberke Station.

MARENNES.—Electric lighting continues to make steady progress amongst the towns and villages in the south-east of France, where water power is happily available. The little town of Marennes and the village of Vierza will shortly be added to the list. The contractor is M. Grejbel.

A NEW LUBRICANT FOR COMMUTATORS.—M. Bandsept informs us that he has found that Marseilles soap makes an admirable lubricant for the commutators of dynamo machines. It should be applied in very small quantity, and will be found highly efficacious in preventing the wear of the brushes.

THE TELEPHONE SUITS IN THE STATES.—According to a telegram in the *Standard* judgment has been delivered in favour of the Bell Telephone Company in its suit against the Globe Company, who were making use of Bassano and Slater's instruments. The defence was based upon the supposed priority of Meucci, the Italian inventor.

TRANS-OCEANIC TELEPHONY.—The New York daily papers want to know why their electricians do not lay a telephone cable to Europe. Mr. Barnum, we learn, "is considering the project," and thinks of ordering a special cable to transmit opera from Paris. We venture to recommend Mr. Barnum to study the writings of Oliver Heaviside.

BANK LIGHTING.—The Union Bank of London, who have for a long time past been considering the question of the electric lighting of their new premises in Princes-street, have now placed the work with Messrs. B. Verity and Sons, of King-street, Covent Garden, under the supervision of Messrs. Drake and Gorham, who are acting as engineers for the bank.

PERSONAL.—We understand that Major-General Webber, C.B., has resigned the position of managing director of the Anglo-American Brush Electric Light Corporation, and has accepted the appointment of consulting technical adviser. Mr. Emile Garcke, who for upwards of four years has been the secretary of the corporation, has been appointed manager and secretary.

A NEW INSULATING PLATE.—An insulating plate which, while very thin and light, is absolutely impermeable to moisture and to air, may be made by taking two leaves of tin-foil coated with a thin layer of gutta percha solution (dissolved in benzine or carbon di-sulphide) and placing them face to face, separated by a leaf of thin paper of close texture. This suggestion is due to M. Bandsept.

FRANCE AND OCEAN CABLES.—The scheme for promoting a cable company under the patronage of the French Government to connect the French Colonies in South America with the mother country, referred to at considerable length in our issue of February 18th, pp. 328, 334, has met with another rebuff. The Chamber of Deputies has postponed *sine die*, by a majority of 237 to 208, the first reading of a Bill to form this company.

THE PROPOSED ELECTRIC TRAMWAY AT BRAY.—The opposition to the proposed electric tramway from the terminus of the Dublin, Wicklow, and Wexford Railway Company to the strand at Bray Head having been withdrawn, the scheme has now received the sanction of the Judicial Committee of the Privy Council, and only awaits the approval of the Lord Lieutenant. We understand that the work will be placed in the hands of Messrs. Woodhouse and Rawson.

THE CARBON TRADE IN AMERICA.—We recently mentioned that the makers of electric light carbons in America had formed a combination to raise the price of carbons to remunerative rates. This move has, however, been met by the electric lighting companies of New York, who have issued a circular proposing the formation of a committee representing the whole of the arc lighting companies to consider the advisability of undertaking the manufacture of their own carbons upon a mutual basis.

SWANSEA.—The Western Counties and South Wales Telephone Company have now extended the Bristol-Cardiff trunk line as far as Swansea, a total length of 116½ miles. The line will shortly be carried on to Llanelly, 12 miles further. At present only a single wire has been completed between Swansea and Cardiff, and that portion of the line is worked through an earth return. In another fortnight, however, it is anticipated that the metallic circuit will be complete throughout. In the meantime conversation between Bristol and Swansea is even now carried on without difficulty.

THE TAMINE ACCUMULATOR.—M. Tamine, of Brussels, has devised an accumulator of the Planté type, in which the liquid consists of a saturated solution of sulphate of zinc, to which is added 50 per cent. of sulphuric acid, 5 per cent. of sulphate of ammonia and 5 per cent. of sulphate of mercury. In making up the cell it is stated that the ingredients should be poured in in the reverse order to that here enumerated. The E.M.F. of the cell is given as 2·3 volts. The addition of sulphates of mercury and ammonia is said to prevent the formation of sulphate of lead on open circuit. The solution appears to be practically identical with that employed in M. Mezerolle's cell.

MALTON.—The Malton proposals have resulted pretty much in the way which might have been anticipated after reading the details which we gave in our last issue; that is to say, out of twenty-four firms who examined the specification of the borough surveyor not a single one proceeded to tender. This result is far more satisfactory than the recurrence of any catch-penny offers such as have too often been made. The Gas Company offered to provide the stipulated number of burners, to consume 5ft. of gas per hour, and to burn 1,700 hours per annum, at a yearly rate of £2. 3s. 6d. per lamp. This offer led to a heated discussion, and the matter still remains unsettled.

PARIS.—It is reported that the Edison Company has applied for powers to open a central lighting station in the neighbourhood of the Théâtre Français. MM. Davy Lepage and Cie. are also negotiating for the establishment of a station in the Boulevard de Strasbourg.—The Paris General Telephone Co. has contracted for supplying the Buenos Ayres Telephone Co.,

Digitized by Google

just formed, with all the requisite instruments, material, and plant for the establishment of the telephone system in the Argentine capital. The Paris Company has also received an order for cables from the Buenos Ayres Municipality, the latter having decided to make an experiment in lighting the city by electricity.

WHAT IS A "SELF-REGULATING" DYNAMO?—A correspondent is anxious to be informed "whether a patent compound-wound self-regulating dynamo-electric machine, in which the brushes are shifted by hand for variable loads, and an adjustable resistance is placed in circuit with the shunt coils, may be considered to possess any marked superiority over machines in which these features are absent?" After carefully considering this curious point raised by our correspondent we are inclined to reply to his question in the negative. But as we are aware that other views are held by (presumably) high authorities, we cannot ask him to attach too much importance to an editorial opinion.

MEETING OF THE INSTITUTE OF MECHANICAL ENGINEERS.—The summer meeting of the Institute of Mechanical Engineers will be held in Edinburgh, on Tuesday morning, August 2, and Wednesday morning, August 3, in the University. The chair will be taken at half-past nine o'clock by the President, Mr. Edward H. Carbutt, in the Natural History Lecture Theatre. The following amongst other papers have been offered for reading and discussion:—"A Description of the Electric Light on the Isle of May," by Mr. David A. Stevenson, of Edinburgh; "On Electro-Magnetic Machine Tools," by Mr. Frederick John Rowan, of Glasgow; "On the Position and Prospects of Electricity as Applied to Engineering," by Mr. William Giepel, of Edinburgh.

SECONDARY BATTERIES IN BELGIUM.—We understand that a syndicate has been formed at Brussels with a view to the acquisition of the whole of the Belgian patents (of any practical importance) relating to secondary batteries. It is believed that arrangements will be concluded with most of the present holders on the basis of an average royalty of two centimes per kilogramme of plates manufactured. The principal object in view is to unite all the valuable features at present distributed amongst numerous patents so as to obtain the best possible form of cell free from all patent troubles and trials. This is a sensible idea, and we shall hope to hear that the negotiations have been carried to a successful issue in time for the International Exhibition which is to take place next year at Brussels.

THE BRUCE ELECTRICAL WAR BALLOON.—On Monday evening last Mr. E. S. Bruce exhibited his electric war balloon at the Kensington Town Hall. The apparatus is intended for aerial signalling. The balloon is of varnished cambric, with a capacity of 2,000 cubic feet. The interior contains a frame, in the form of a ladder, suspended in its centre, holding six incandescent lamps of the Edison and Swan type, of 25 volts, the current being conveyed to the frame by a flexible double cable. The lamps are controlled from a switch board, the contacts being of carbon instead of platinum, and the balloon is held captive by a line of Italian hemp capable of bearing a breaking strain of 25 tons. The apparatus is worked with an E.P.S. battery of 25 cells. We understand that the trials which have been made at Chatham have convinced the military authorities of the utility of the idea. The apparatus exhibited has been made for the Belgian Government.

THE PARIS, 1889, EXHIBITION: PROPOSED NOVEL ELECTRIC RAILWAY.—In a paper read by M. Eugène Hénard before the French Society of Architects, it has been proposed to lay down a "continuous" electric railway or "carrying platform" around the whole of the grounds of the Paris Exhibition. The idea is to lay the rails in a trench of such a depth that an ordinary flat-topped railway waggon just reaches the surface of the ground; the whole circle would then be filled with a train of such waggons coupled close together and provided with a continuous floor. This train is to be driven at a walking pace by a number of electric motors placed at intervals upon or underneath the waggons. Passengers can thus step on or off at any point, and no fares would be charged except for seats. The working of the line would be controlled from signal boxes placed at suitable distances, from each of which the train may be stopped at any moment by opening one of the main leads. The idea strikes us as a rather good one, and there should be no difficulty in carrying it out with entire success, and with great convenience to visitors.

SEILER'S HOTEL ANNUNCIATOR SYSTEM.—In order to reduce the number of electro-magnetic drops which are required in fitting a large building with electric bells and annunciators, Mr. P. Seiler (of San Francisco) has brought out a system whose merit consists chiefly in the use of a limited number of annunciators to indicate a much larger number of rooms. This is carried out by placing the numbers of the rooms on fixed tablets arranged in a square or rectangular form, and having two rows of annunciators which run along the top and down one side of the board, so that by the fall of any two of the annunciator drops a particular number is indicated. The arrangement for actuating the drops is ingenious. When a call is first received an annunciator in the horizontal row only is seen to fall. The signal is then acknowledged by the attendant, who presses the key which is found at the bottom of the vertical row of numbers indicated by the drop. The pressing of this key causes the second drop in the vertical row of annunciators to fall, indicating the number of the room, and at the same time giving an acknowledgement of the signal.

METHOD OF PREVENTING THE BLACKENING OF INCANDESCENT LAMPS.—Mr. Ed. P. Thompson has found that the blackening of the glass of incandescent lamps is chiefly due to the carbon particles which are driven off on first closing the circuit when the filament obtains a static charge. In order to avoid this Mr. Thompson has made lamps in which the filament surrounds a loop or stem of copper wire, which passes through the stem of the lamp and is connected to earth; the wire being also provided with several points which project towards the filament. The result is that when the static charge is received the carbon molecules tend to be projected upon the wire, and the blackening of the glass is prevented. Mr. Thompson's theoretical explanation of the effect is certainly sufficiently plausible to merit consideration, but it appears to us that if this view were correct it would follow that incandescent lamps supplied with alternating currents should blacken much more rapidly than with continuous currents, and their life should be much shorter. We have not learnt that such a result has ever been observed, and it would almost appear that this objection is fatal to the static charge theory.

HOW TO FORM A PRIMARY BATTERY COMPANY.—The following instructions upon this interesting and important subject are taken from an American technical journal. The business appears, however, to be tolerably well understood in certain quarters on this side the Atlantic:—"Organise under the laws of the State of Maine; 10,000 shares of stock, par value, $100 per share. Offer to let in your friends on the ground floor at $1 per share. Print some circulars, setting forth the millions [not] made in primary batteries, in times

Digitized by Google

gone by; explain indefinitely that a new discovery has been made of an [old] chemical by the aid of which current can be produced for domestic incandescent lighting. There are as gullible investors as ever were caught, and they will bite. Delays are convenient—carbons not ready; cups too porous. Keep this up as long as possible, and then get some batteries, and run one or two incandescent lights far above their candle power. Do not let them burn but a few moments at a time, and a 5 candle-power run up to 25 candle-power will last some days. Comment on the whiteness and steadiness of the light. When people apply for batteries convince them of their folly, and induce them to purchase stock. When the enthusiasm is at its height sell the stock, and be conveniently called to some other section of the world for a year. On returning repeat the same operation."

VULCABESTON.—Vulcabeston is the name of a new material which professes to combine all the valuable qualities of asbestos and india rubber. It is described as forming a substance of the toughness of horn, although it can be made of any degree of flexibility. It is a non-conductor of electricity, and stands the severest test of acids, steam, gases, &c. One of the most important uses of the new material is as a moulded piston rod packing ring, made to fit any sized rod or stuffing box, and to be sprung in place with a slight pressure, one or more rings being used as desired, and forming a perfectly tight steam joint. These rings do not wear the rod, and they are self-lubricating. The first set made of these rings has been in use over eleven months, in a Hartfort, Conn., manufactory, on an engine run at 280 strokes per minute, and is still in perfect order. Vulcanised asbestos piston rod packing in the form of flexible rope, of all sizes, will not shrink or blow out, and is especially adapted for use on locomotives and ocean steamers, and in other places where loss of time in repacking is of the greatest consequence, and where the use of ordinary steam packings would consequently be entirely inadmissible. And it is claimed that in consequence of its great strength and durability it can be used wherever metallic packings have heretofore been necessary. If all this is true the new material may be expected to do good service in connection with engines for central station electric lighting.

GALLANT CONDUCT OF TWO ELECTRICIANS.—We have pleasure in recording two very gallant rescues from drowning which took place last week at Waterford, and of which Messrs. Pope and Bate, of the firm of Laing, Wharton and Down, were the heroes. These gentlemen are at present engaged in the erection of a Thomson-Houston plant for lighting the City of Waterford, and were bathing in the bay on Thursday morning, although the water was somewhat rough. On the left hand side of the bay a strong under-current exists, and after being in the water some time Mr. Bate observed a man in an unconscious condition and drifting out to sea in the current. Shouting to his colleague, they both dashed to the rescue. The drowning man was first reached by Mr. Pope, who, after an exhausting struggle for ten minutes in the heavy seas, brought him safely to land. Mr. Pope found himself completely done up and unable to stand, but while being attended to by Mr. Bate, cries were again heard from the sea, and a priest, Father Dooley, was discovered vainly endeavouring to support another half-drowned individual whom he had gone to rescue. Mr. Bate seized a life-buoy, and again plunging into the water, succeeded, with the aid of a bystander named Phelan, in bringing both men safely to shore. The individual saved by Mr. Pope was a medical student named Keogh, and in the second case Mr. O'Farrel, a ship-broker, was concerned. We are glad to hear from Messrs. Laing, Wharton, and Down that they are taking steps to bring the matter before the Royal Humane Society.

THE PARTNERSHIP BETWEEN GAS AND ELECTRICITY IN AMERICA.—The annual report of the American Electric Manufacturing Company contains the following reference to their alliance with the gas interest:—"The past year has demonstrated the soundness of the opinion long entertained and persistently advanced by the officers of this company, that the gas and electric lighting interests of the country should co-operate instead of antagonising each other. Gas lighting companies have finally come to recognise the fact that their interests are best subserved by the combination of the two illuminants for local lighting purposes under one management, and that it is far better for them to add electric lighting apparatus to their present plants, and thus prepare themselves to meet the entire demand for illumination in their respective localities than to permit others to introduce the newer and more brilliant illuminant as a rival to gas. They have found that such a combination is not only practicable and profitable, but that the adoption of electric lighting by gas companies practically excludes competitors because of the superior economy with which such companies can operate electric lights in connection with their established gas business. Other electric lighting companies have at last perceived that the combination is inevitable, and are tardily endeavouring to obtain the adoption of their respective systems. But the American Company is pretty generally recognised as the pioneer in this direction, and will naturally enjoy the largest share of the patronage of the gas companies, especially in view of the superiority of its apparatus. Recognising the great importance of the company's future dealings with this extensive and important industry, the trustees established a special gas department of the company's business, and have placed in special charge thereof one of the most experienced, successful, and widely known gas engineers in the country."

ELECTRIC TRACTION.—Considerable light is shed upon the causes of the very partial success of electric traction on the Brussels tram lines when we learn that an attempt was made to use a dynamo of old-fashioned type as a motor. Upon the long and steep gradients of the Brussels line the torque upon the armatures must be very great indeed, and it was little short of folly to expect an armature built for a totally different purpose to withstand the strain. Whatever points of divergence have yet to be settled in the theory of dynamos and motors, it is yet fully understood—or at any rate it is high time that it should be—that a motor which is geared in a positive manner, and is liable to be started under a heavy load, must be designed, both mechanically and electrically, on the basis of an output far exceeding its normal rate of working. An old-fashioned dynamo is simply useless for work of this description. The Brussels Company having now fully convinced themselves upon this point, we understand that it has been decided to employ motors of English make, and M. Julien was recently in this country making inquiries. We are pleased to learn that the Julien cells continue to give satisfaction. Each car, weighing with its load of passengers 16,500lb., carries in addition a weight of 3,300lb. of accumulators. This ratio of weight of battery to total weight is slightly lower than that obtained by the Electric Traction Syndicate (as described in another column), but this in part arises from the fact already alluded to, that the motor is too light for its work. But as we are not aware of the total capacity of the cells in the former case, the comparison is not of much value. The battery consists of 120 cells, which are coupled to a switch, so as to

Digitized by Google

give 60, 120, 180, or 240 volts, as may be desired. The plates are reported so far to have behaved very well indeed. We trust that the present suspension of the service will not be of long continuance, and we fully anticipate that with suitable motors the success of the company will become indisputable.

THE ELECTRIC LIGHT IN THE FAR WEST.—In the smaller towns of the Western States of America the electric light continues to make steady progress, and its introduction is greeted with an enthusiasm which is positively delightful. The *Roodhouse Evening Eye* thus describes the first lighting up of an arc lamp plant in the streets of its native town, and it must be said that the writer rises to the height of the occasion: "A few moments of breathless expectation, and a great cheer goes up as the carbons break into flame, as with the quickness of lightning the dazzling arcs of flame burst forth between the carbon points, as if the genius of electricity, angry to find his course opposed, had leaped the barrier, white with rage. The effect was wonderful, and far exceeded the expectations of all. It was well calculated to arouse enthusiasm." After this it was of course impossible to refrain from "dropping into poetry." Here is the result:—

PANSY'S PIECE.

No more in darkness will we grope
  Along the gloomy street,
And on a narrow walk collide
  With every one we meet.
The wonderful electric light
  Our highways will illume,
While all the towns for miles around
  Are talking of our boom.
Behold it gleaming in the sky,
  With scintillations bright,
Like some resplendent jewel in
  The shirtfront of the night.
The pale moon shines with sickly hue,
  And hides her yellow face,
The spark electric rules the night,
  And has usurped her place.
And burning Phœbus, lord of day,
  When this new sun he sees,
Withdraws himself to other parts,
  And shines on the Chinese.

POROUS CELLS MADE OF VULCANISED FIBRE.—According to our contemporary, *L'Electricien*, it has recently been discovered by M. de Rufz that notwithstanding the excellent insulating properties of vulcanised fibre when dry, yet after long soaking in "a liquid" (whether pure water or not does not appear) it swells considerably and becomes very sensibly porous, so much so as to be admirably adapted for use in two-fluid primary batteries, or in secondary cells of the Faure type as a separator between the plates. For each of these purposes it is said to be well adapted, because of its very low electrical resistance. We may, however, remark that the apparent resistance of a porous pot is in reality the resistance of the liquid which it contains in its interstices, and therefore varies with the nature of the liquid in which it has been soaked. Hence the measurement of the apparent resistance of a porous pot is an index of the rate at which liquids can diffuse through its walls, so that for primary batteries there will in some cases be a limit below which it is not advantageous to reduce the resistance of the cell. On the other hand, for secondary batteries, and also for primaries used in electric lighting, where the liquids are presumably exhausted before much diffusion can have taken place, the new material seems to give promise of usefulness. At the Ecole de Physique it was found that the internal resistance of a Bunsen cell, which measured ·06 ohm, with an earthenware pot, was reduced to rather less than 0·03 ohm on the substitution of a vulcanised fibre cell ½ mm. in thickness. One advantage cells of this description would undeniably possess, that is, in the reduction of weight, and M. de Rufz attaches considerable importance to this point as facilitating the employment of primary cells for the propulsion of tricycles, balloons, and boats. It is, however, necessary to add this caution; vulcanised fibre dissolves rapidly in the solutions of certain salts, amongst which are the bichromates of potassium and of sodium, and it is also attacked by concentrated sulphuric acid, although in the dilute acid it remains unaffected.

LEAMINGTON.—The engine and boilers for the Leamington central station are now in place, and the dynamos (of the Chamberlain and Hookham type) will shortly be ready. The contract for laying the underground cables is in the hands of Mr. J. Fell, and considerable difficulty has been experienced owing to the number of gas and other pipes already in the ground. We understand that a satisfactory number of applications has been received, and it is hoped that the installation will be at work before the end of August.—On the 27th inst. Major-General C. Phipps Carey, one of the Local Government Board inspectors, held an inquiry at Leamington respecting the application of the Town Council for leave to borrow three sums of £1,033, £1,230, and £500. Mr. Passman explained that the loan of £1,230 was required for electric lighting purposes. The council had entered into arrangements with the Electric Lighting Company for lighting the Parade, the Town Hall, Free Library, and Pump Rooms. It was not proposed to dispense with the present arrangements for the supply of gas, so that if the electric light should not prove satisfactory they could revert to gas. Their contract with the gas company included their right to experiment with any new light which may be brought out, and, on the other hand, their agreement with the Electric Lighting Company could be terminated at the close of 1888 if desirable. The Corporation paid none of the cost of the machinery and apparatus for supplying the electric light. They only paid for their connections and their lamps. The loan included £475. 11s. 6d. for the Town Hall and Free Library, £212 for the pump rooms, and £542. 10s. connected with the lighting up the Parade from the bridges in Bath-street up the Parade to Christ Church, a distance of about a quarter of a mile. As proof of the *bona fides* of the Electric Lighting Company, Mr. Passman said they were expending upwards of £10,000 upon their works. Mr. Gilbert said the total outlay for this company would be nearly three times the amount named by Mr. Passman. The quality of the light to be supplied to the public buildings, Mr. Passman explained, would be sixteen candle-power, and the cost at the rate of 4d. per Board of Trade unit of 1,000 volt-ampere hours. The inspector will report to the Local Government Board in due course.

BURNING OF THE TELEPHONE EXCHANGE AT PITTSBURG.—On the morning of the 10th inst. a fire broke out in a block of buildings at Pittsburg occupied by the Telephone Company, the Western Union Telegraph Company, and the Printing Telegraph Company. The telephone exchange was completely destroyed, the whole of the instruments and batteries of the Western Union Company were burnt, and much damage was done to the plant of the Printing Telegraph Company. It is not known how the fire originated, but it was first discovered under the Western Union switch-board, and it is supposed that rats or other vermin had eaten off the paraffin and cotton covering, leaving the bare wires in contact with woodwork. An alarm was sent in from two boxes, and the fire department

Digitized by Google

responded promptly, but as the flames were in the upper floors, which were surrounded by a labyrinth of line wires, the firemen were much hindered by having to cut their way to the building. There were eight to nine thousand cells of battery on the top floor, and these played an important part. In Pittsburg the almost obsolete practice of filling up battery cells with signal oil was followed, about eight barrels of it being used in the room. This oil, of course, caused the fire to burn more fiercely and rapidly, while the fluids from the broken batteries poured down the inside and outside of the building, staining everything a dirty yellow. The telegraph company immediately transferred their business, so far as possible, into the eight circuits of the Mutual Union, and ordered a carload of supplies express from New York. In four days they had all their wires working. But with the telephone company such promptness in resuming business was impossible, because outfits for telephone exchanges are made to order, and cannot be had on very short notice. One of the eight sections of 2,000-wire multiple boards was ruined, and the other seven had to be taken apart and sent to Chicago for repairs. The exchange at Pittsburg is the third large telephone exchange in America that has been destroyed by fire, the others being Montreal and Toronto. After the burning of the Toronto exchange it was suggested that, in view of the delay in getting large switch-boards in emergencies, it would be a wise thing in the way of insurance if a number of telephone companies should jointly buy a complete central office outfit, to go to the first place burned out. The plan was favourably considered, but no action has been taken.

THE TELEPHONE STATISTICS OF EUROPE.—The International Bell Telephone Company has compiled the following list, which shows the number of telephones in use at the end of 1886 in the countries in which it operates :—

Belgium.

Brussels	998	Le Louvière	22
Antwerp	1,043	Liége	438
Charleroi	216		
Ghent	419		
Verviers	396	Total	3,532

Total length of line wire, about 6,900 kilometres.

Holland.

Amsterdam	1,263	Arnheim	127

Total length of line wire, about 12,500 kilometres.

The largest increase of subscribers was in Belgium, about 18 per cent., and in Russia about 15 per cent., as compared with the figures of 1885. The other countries show less progress. The average increase of all the towns which are worked by companies allied with the International Bell Telephone Company (Limited), of New York, is about 10 per cent., against 9 per cent. in 1885, and 9 per cent. in 1884. In the above-mentioned countries there are, besides, a certain number of minor telephone exploitations. Thus, we find in Belgium seven small towns with telephone exchanges, having a total of about 550 subscribers. In Italy there may be twelve such small towns with the telephone, about which no reliable data can be obtained. In Russia six other towns of more or less importance have telephone installations, whose number of subscribers may be put down as 600 in the aggregate up to the end of 1886.

THE CONDUCTIVITY OF WIRES.—In an interesting paper presented by M. Mialaret to the *Société Internationale des Electriciens*, the author points out that our measurement of the specific resistance of wires of different metals is open to some ambiguity, unless it is stated whether we refer as a standard to a wire of given length and sectional area, or of given length and weight. In this country samples of copper and bronze are frequently referred in the trade both to the foot-mil. and foot-grain as determined 30 years ago for "pure" copper by Mattheissen, the result being that, when the comparison, as is most usual, is made by weight, improved processes now frequently enable manufacturers to turn out wire of 101 or 102 per cent. conductivity. But the improvement in wires of so-called "high conductivity" results, as a matter of fact, as much or even more from the greater density which can now be given to the metal as from its greater purity. It follows that comparisons with the two standards of weight and volume no longer agree amongst themselves, since the density of the metal differs so considerably from that of pure copper. In fact, the actual conductivity of the wire referred to unit volume in many cases *considerably exceeds* the quotation taken with reference to the standard of weight; and although it is much more convenient to weigh a quantity of wire than to ascertain its length by actual measurement, yet it is evident that unit volume rather than unit weight is the proper standard of reference; not only is it the recognised theoretical standard, but it is usually of more immediate practical importance. The divergent results given by the two standards of reference are well illustrated by the following table of measurements, by M. Mialaret, furnished by three different samples of wire of high conductivity :—

	1.	2.	3.
Specific gravity	8·897	9·32	9·6
Conductivity for equal volumes.	102·4	106·7	110·8
„ „ „ weights..	101·7	101·2	101·6

These percentage conductivities are taken in reference to Matthiessen's standards. It would appear from this that manufacturers may be unwittingly doing themselves an unjustice in the statement of percentage conductivities. The remedy is simple enough; the employment of percentage quotations is utterly unnecessary, and is a mere survival from the period before any uniform standard of resistance had been accepted. All we want to know is the actual resistance in ohms of a given volume or a given weight of wire of given sectional area, and at a definite temperature. If, however, the standard of weight be preferred, then it is necessary for purposes of comparison to know also the specific gravity of the metal. We should thus at once get rid of the unscientific and somewhat absurd method of quoting 101 per cent. conductivities, while the uniform quotation of actual resistance will often save calculation. It is true that in this country many of the leading firms already follow this method, but it is still by no means universal abroad, and in any case M. Mialaret will have done good service in calling attention to the discrepancy between the two different customary standards of reference.

give 60, 120, 180, or 240 volts, as may be desired. The plates are reported so far to have behaved very well indeed. We trust that the present suspension of the service will not be of long continuance, and we fully anticipate that with suitable motors the success of the company will become indisputable.

THE ELECTRIC LIGHT IN THE FAR WEST.—In the smaller towns of the Western States of America the electric light continues to make steady progress, and its introduction is greeted with an enthusiasm which is positively delightful. The *Roodhouse Evening Eye* thus describes the first lighting up of an arc lamp plant in the streets of its native town, and it must be said that the writer rises to the height of the occasion: "A few moments of breathless expectation, and a great cheer goes up as the carbons break into flame, as with the quickness of lightning the dazzling arcs of flame burst forth between the carbon points, as if the genius of electricity, angry to find his course opposed, had leaped the barrier, white with rage. The effect was wonderful, and far exceeded the expectations of all. It was well calculated to arouse enthusiasm." After this it was of course impossible to refrain from "dropping into poetry." Here is the result:—

PANSY'S PIECE.

No more in darkness will we grope
  Along the gloomy street,
And on a narrow walk collide
  With every one we meet.
The wonderful electric light
  Our highways will illume,
While all the towns for miles around
  Are talking of our boom.
Behold it gleaming in the sky,
  With scintillations bright,
Like some resplendent jewel in
  The shirtfront of the night.
The pale moon shines with sickly hue,
  And hides her yellow face,
The spark electric rules the night,
  And has usurped her place.
And burning Phœbus, lord of day,
  When this new sun he sees,
Withdraws himself to other parts,
  And shines on the Chinese.

POROUS CELLS MADE OF VULCANISED FIBRE.—According to our contemporary, *L'Electricien*, it has recently been discovered by M. de Rufz that notwithstanding the excellent insulating properties of vulcanised fibre when dry, yet after long soaking in "a liquid" (whether pure water or not does not appear) it swells considerably and becomes very sensibly porous, so much so as to be admirably adapted for use in two-fluid primary batteries, or in secondary cells of the Faure type as a separator between the plates. For each of these purposes it is said to be well adapted, because of its very low electrical resistance. We may, however, remark that the apparent resistance of a porous pot is in reality the resistance of the liquid which it contains in its interstices, and therefore varies with the nature of the liquid in which it has been soaked. Hence the measurement of the apparent resistance of a porous pot is an index of the rate at which liquids can diffuse through its walls, so that for primary batteries there will in some cases be a limit below which it is not advantageous to reduce the resistance of the cell. On the other hand, for secondary batteries, and also for primaries used in electric lighting, where the liquids are presumably exhausted before much diffusion can have taken place, the new material seems to give promise of usefulness. At the Ecole de Physique it was found that the internal resistance of a Bunsen cell, which measured ·06 ohm, with an earthenware pot, was reduced to rather less than 0·03 ohm on the substitution of a vulcanised fibre cell ½ mm. in thickness. One advantage cells of this description would undeniably possess, that is, in the reduction of weight, and M. de Rufz attaches considerable importance to this point as facilitating the employment of primary cells for the propulsion of tricycles, balloons, and boats. It is, however, necessary to add this caution; vulcanised fibre dissolves rapidly in the solutions of certain salts, amongst which are the bichromates of potassium and of sodium, and it is also attacked by concentrated sulphuric acid, although in the dilute acid it remains unaffected.

LEAMINGTON.—The engine and boilers for the Leamington central station are now in place, and the dynamos (of the Chamberlain and Hookham type) will shortly be ready. The contract for laying the underground cables is in the hands of Mr. J. Fell, and considerable difficulty has been experienced owing to the number of gas and other pipes already in the ground. We understand that a satisfactory number of applications has been received, and it is hoped that the installation will be at work before the end of August.—On the 27th inst. Major-General C. Phipps Carey, one of the Local Government Board inspectors, held an inquiry at Leamington respecting the application of the Town Council for leave to borrow three sums of £1,033, £1,230, and £500. Mr. Passman explained that the loan of £1,230 was required for electric lighting purposes. The council had entered into arrangements with the Electric Lighting Company for lighting the Parade, the Town Hall, Free Library, and Pump Rooms. It was not proposed to dispense with the present arrangements for the supply of gas, so that if the electric light should not prove satisfactory the could revert to gas. Their contract with the gas company included their right to experiment with any new light which may be brought out, and, on the other hand, their agreement with the Electric Lighting Company could be terminated at the close of 1888 if desirable. The Corporation paid none of the cost of the machinery and apparatus for supplying the electric light. They only paid for their connections and their lamps. The loan included £475. 11s. 6d. for the Town Hall and Free Library, £212 for the pump rooms, and £542. 10s. connected with the lighting up the Parade from the bridges in Bath street up the Parade to Christ Church, a distance of about a quarter of a mile. As proof of the *bona fides* of the Electric Lighting Company, Mr. Passman said they were expending upwards of £10,000 upon their works. Mr. Gilbert said the total outlay for this company would be nearly three times the amount named by Mr. Passman. The quality of the light to be supplied to the public buildings, Mr. Passman explained would be sixteen candle-power, and the cost at the rate of per Board of Trade unit of 1,000 volt-ampere hours. The inspector will report to the Local Government Board in course.

THE JUBILEE OF THE ELECTRIC TELEGRAPH.

Fifty years ago, on July 25th, 1837, a few scientific men carried out a successful experiment between Euston and Camden Town, which was repeated the next day before a larger audience. From such a small beginning has grown the wonderful network of land telegraphs, of submarine cables, and of telephone lines that we see around us. Familiarity in this case has certainly led the general public to take for granted "what is is right," and to forget, to a great extent, how and by whom such grand results have been obtained.

On Wednesday last a dinner was held at the Holborn Restaurant under the presidency of the Postmaster-General, the Right Hon. Henry Cecil Raikes, M.P., to celebrate in the approved English fashion the Jubilee of the Electric Telegraph. The thanks of the telegraphic world are due to Edward Graves, Esq., C. H. B. Parey, Esq., C.B., and to W. H. Preece, Esq., F.R.S., for the initiative they took, and the unceasing efforts they made to worthily celebrate this anniversary. It is not necessary here to refer to the work of the executive committee or the general committee. That the work was well done the result testifies. Of all the gatherings held in this year of grace 1887 it is probable that none will be of greater historic interest, or will live longer through the endless vista of time than the one we now record. Elsewhere we give a complete list of all those who took part in this memorable dinner. It may be that a few names are given in error as of those present, the list being taken from the amended list of the executive committee just previous to the commencement of the dinner, and at the last moment some who had accepted found it impossible to attend. Our endeavour is to place on record the name of each person who took part in this Jubilee celebration, and we think telegraphists in years to come will look back with interest upon the list.

Lack of space prevents our commenting upon the work of individuals; but it may be accepted that this was a thoroughly representative assembly. A few celebrated workers, whom their colleagues would have been delighted to honour, were from various causes not able to be present, an unavoidable circumstance much to be regretted.

At the conclusion of the dinner Mr. W. H. Preece, F.R.S., announced that letters of regret had been received from the following gentlemen:—Marquis of Salisbury, Lord John Manners, Viscount Cross, Mr. W. H. Smith, Sir Henry Holland, Sir Wm. Grove, Sir Daniel Gooch, Sir Julian Goldsmid, Sir Algernon Borthwick; M. Mascart, Paris; M. Coulon, Paris; M. Fribourg, Paris; M. Delarge, Brussels; M. Koller, Budapesth; and M. Hofstede, The Hague.

Other letters and telegrams of congratulations and regret were referred to, of which we give the following:—

DEAR SIR: Your favour of the 1st, by which you have transmitted me an invitation of the General Committee to a dinner at the Holborn Restaurant, London, on the 27th, in memory of the 50th anniversary of the first practical application of electricity to telegraphy in England, has been duly received.

Thanking you most heartily for the honour thus shown me, I must to my utmost regret add that the unsatisfactory state of my health prevents me from venturing upon a sea voyage. I shall, therefore, miss the beautiful and momentous festivity in the fatherland of Cooke, Wheatstone, Thomson, Hughes, Daniell, Grove, and numerous others, whose names are for ever associated with the rise and progress of telegraphy. Unwillingly I must forego the opportunity to shake hands with many dear old friends and excellent colleagues. But though absent in body, I will be there in mind, and from my heart send you my best wishes. I may ask you to give my compliments to the President of the Jubilee, my esteemed colleague, the Right Hon. Cecil Raikes, M.P.

Please accept my apologies for tarrying so long with my answer, and believe me to be, yours truly,

Berlin, W., July 21st, 1887. DR. V. STEPHAN.

SIR: I have the honour of acknowledging the receipt of your letter of June 30th, inviting me to the dinner which is going to be held on the 27th of this month, in celebration of the fiftieth anniversary of the first practical application of electricity to telegraphy in England; and in reply, I beg to say that much as I desire to assist personally on so noteworthy an occasion, I find, to my very great and sincere regret, that I am unable to give myself that pleasure in consequence of other pressing engagements, which, unfortunately in this instance, admit of no postponement. I beg you will kindly accept my assurance, therefore, that were it not for these circumstances, I would gladly have availed myself of your invitation, for which I tender you herewith my sincere thanks; and I remain, Sir, your most obedient servant,

Berlin, 12th July, 1887. DR. WR. SIEMENS.

"Pray accept heartiest congratulations on Jubilee of the telegraph in England. The progress of telegraphy on this side of the globe has comparatively been no less wonderful than that in the old country during the thirty years which have elapsed since the opening of the first line, seven miles long. In New South Wales only we have erected 20,797 miles of wire, and our returns last year show that we transmitted 2,661,126 messages, which yielded a revenue of £158,127. The number of our stations is 425, and 1,200 hands are employed in the administration of the department. The lines connecting the colony with Victoria and Queensland are worked on the quadruplex system—that system is also adopted on many of our local circuits; the line to South Australia is duplex. In telephony, which is a branch of the telegraph department and entirely in the hands of the Government, our list of subscribers numbers 735; last year's revenue from this source amounts to £1,740.

"Our railway telegraphs include 203 stations and 2,500 miles of line on the section. On double lines where the traffic is very heavy Preece's block system is operated with a success which cannot fail to gratify the eminent and genial inventor. Whilst our material progress has thus been advancing by rapid strides, there has sprung up amongst us and grown into vivacious maturity that brotherhood of feeling towards our fellow-workers throughout the world which seems characteristic of telegraph men; but the line of least resistance, and therefore that which carries the greatest share of the current of our sympathy, is that which connects us with the land whence so many of us have come, and which, although separated by great spaces of time and distance, is yet thought and spoken of by us as the dear old home where telegraphy now holds its first Jubilee. "CRACKNELL, Sydney."

"Many and heartiest congratulations on the Jubilee of the electric telegraph from myself and co-workers in South Australia. In fifty years this offspring of science has, in the direction of peace, revolutionised the whole world, brought the most distant portions of the British Empire within speaking distance, and rendered federation not only possible, but easy of accomplishment. May the circuit which now unites us ever promote the kindest feelings in the large army of British telegraphists, and insulate us from all harm! South Australia, unaided, electrically bridged over the Australian continent, and with a population of but little over 300,000, has erected 10,300 miles of telegraph at a cost of £1,101,477, including buildings. God save the Queen! "C. TODD, Adelaide."

"Agent, Adelaide, to Preece.—From JAMES, Melbourne:—Telegraphs established Victoria, March, 1854, being first south of line; year 1886, over 2,000,000 messages transmitted; revenue, £102,000; miles wire, 15,000; cost construction, £450,000; tariff, six pence minimum six words, penny additional word, address and signature free; number stations, 467; staff, over 2,000. Population 1854, 312,000; 1886, 1,003,000. Congratulations."

"The British electricians in the United States, with American friends and associates, send hearty congratulations and greetings to company assembled to celebrate this day the memory and work of Cooke and Wheatstone and the Jubilee of the Telegraph. All rejoice in an anniversary which finds New York as near to London as Camden Town was to Euston-square 50 years ago, and which sees the great name of Wheat-

Digitized by Google

stone honoured the world over in connection with inventions that have made nations neighbours, that have broken down prejudice, and promoted knowledge, friendship, and peace to the whole universe. God bless Old England!

"GEO. G. WARD, for the Committee.

"New York, July 27th, 1887."

"The birth of the Indian Telegraph occurred in May, 1839, when O'Shaughnessy, experimenting in Calcutta, worked an electromagnetic needle, a chemical recorder and two synchronous alphabetical dials through an iron wire line of 23 miles; it is thus 48 years since he started India well in the race for Jubilee honours, and the Indian Telegraph Staff send hearty greetings, and join in your celebration to-night.

"SIR ALBERT CAPPEL."

"Tasmania.—Telegraph: 1,151 miles of poles, 1,730 miles of wire, 109 stations, Morse instruments, telephones, brake combination. Exchanges: Hobart, 200; Launceston, 162. Members heartily join in celebration of Jubilee."

"Your Antipodes sends congratulations. May Macaulay's prophecy never be realised!

"C. LEMON, Wellington, New Zealand."

"GAHAN, of Perth, Western Australia, joins in Australian congratulations on Jubilee."

"From KINGSFORD, Lima.—Members of Society of Telegraph-Engineers and Electricians in Mexico and Peru desire heartiest Jubilee greetings."

"Congratulations from Queensland. Through to Cape York next month, 1,870 miles, all the way for a shilling."

"Eckert to Preece.—Pray accept for yourself and the other members of the telegraphic fraternity who are present the warm congratulations of Dr. Green and myself on the occasion of your Jubilee dinner. We who are so busily engaged in the development of the telegraph are perhaps the least conscious of the multitude of blessings which have followed and which still follow in its train. We cannot divest ourselves of the arduous toil and the exacting details which have marked its progress step by step, and which spoil for us the complete perspective of the great results which have been achieved. It, however, seems almost incredible that my practical experience should cover a period which began with short circuits that succumbed to almost every summer shower, and has now reached a point when we frequently send, almost irrespective of weather, about 50,000 words in the evening over direct circuits nearly 4,000 miles long for publication in the San Francisco papers the next morning. In fifty years the telegraph in America has grown to the gigantic proportions of the Western Union Company—that is, 475,000 miles of wire, or enough to girdle the earth nineteen times. This development has enlisted the endless endeavour of some of the brightest intellects of the age, and represents everywhere an equal indebtedness to the untiring loyalty and zeal of the rank and file of the telegraphic profession. The telegraph has been one of our greatest pioneers wherever man has gone. Into the wilds in search of treasure, or to cultivate the soil, he has taken it with him. At first it has supplied his necessities nearly as soon as they have arisen, and then it has brought him luxuries almost as soon as he has desired them. While the railroads have been the means of quicker transportation, the telegraph has been, if I may so call it, the nervous intelligence which has informed their movements, enlarged their facilities and enriched their results. In a few months by these means towns have sprung up in the virgin forests or on the desolate plains, and in a few years they have by the same means developed into opulent cities, giving prosperity and contentment to thousands. Add to this the achievement of submarine telegrapy, and are we not identified with, and, in fact, part and parcel of, one of the greatest powers for good not only of this marvellous nineteenth century but of all time? The kinship of nations has been strengthened by the telegraph, and most of all between England and America the incessant streams of messages across the Atlantic bear silent witness to the bonds of affection, sympathy, and interest which bind the two peoples together. The next generation of telegraphers will start with results which were undreamed of to us in the infancy of the art. Let us hope that they will not disdain to remember with some degree of interest and sympathy the debt which their perfection owes to the perplexities, bordering sometimes on despair, which accompanied the early efforts of the senior ranks to which you and I belong.

"ECKERT."

The CHAIRMAN, who was received with prolonged cheers, then said: Gentlemen—The first toast upon every public occasion of this kind during every year of the long reign among her faithful subjects has been "The Health of Her Majesty the Queen" (cheers), and I am happy to think that upon no occasion and in no year can that toast have been more appropriate than it is on the occasion which brings us here to-night to celebrate the Jubilee of perhaps the greatest scientific discovery in its applied form that has ever, as yet come to improve the lot of man (applause); and it is a happy coincidence that the Jubilee of the Telegraph so closely coincides with that of the best of Sovereigns (cheers). During the fifty years which have elapsed since Her Majesty Queen Victoria ascended the throne of this realm we have come to associate her so closely with that triumphant march of progress and, on the whole, of peace which has distinguished that long period that we sometimes run almost some risk of ceasing to appreciate, as we ought to do, her own individual merits and virtues as a woman and as a Sovereign (applause); but I feel that the events of this past year have brought so largely into view the personal aspect of English royalty, that it is with renewed energy and, if possible, with redoubled loyalty that I beg you to drink "The Health of Her Majesty the Queen."

The toast was honoured with the greatest enthusiasm, the entire company afterwards joining in the singing of the National Anthem.

The CHAIRMAN: Gentlemen—There is a somewhat graceless proverb that tells us that there is nothing sacred to an engineer. I venture to believe that that is a misrepresentation of a body of men who at least know how to reverence all that is deserving of respect (applause), and I wish before we proceed to any other of the toasts upon our list to ask you to join in an expression of reverence for those great and illustrious men, many of whom have ceased to be among us, but some of whom I hope still survive, and I ask you to drink in solemn silence as a mark of respect and reverence "To the Memory of the Pioneers of Telegraphy."

The toast having been duly honoured,

The CHAIRMAN said: Gentlemen—It now falls to me to propose to you the toast of the evening, and I may, I think, well say that no one ever approached a task of great interest and great magnitude with a fuller sense of his own unworthiness to discharge it. I see before me the men who have done so much to extend and to popularise the progress of science, and I must ask you to be tolerant if, in the few observations which I shall venture to address to you, I show how little the labours and engagements of political life enable one to follow that great march of scientific progress whose Jubilee, and especially of the walk of science, we are celebrating here to-night, and I feel this, perhaps, all the more because I am conscious that among my predecessors in the office which I now hold there is at least one man present whose name is a household word wherever science is known and venerated, and who would be infinitely more competent to discharge the duty which has fallen upon me. But as you will have the privilege of listening to Sir Lyon Playfair when he proposes another toast I will venture without further apology to commend to you to the best of my power the toast which forms the subject of our gathering here to-night. Gentlemen, you are all aware that last Monday was the fiftieth anniversary of the first occasion on which the electric telegraph was brought into operation in England (applause), and we have most of us, perhaps, read of that tumultuous sensation which the great Wheatstone confesses to have experienced

when the message which he sent on that little journey from Euston-square to Camden Town was sent back to him by Mr. Cooke (cheers). I am, perhaps, not exaggerating the importance of the occasion when I venture to say that that evening as Wheatstone sat in the small cupboard of an office, communicating with his colleague at a distance of some two miles, was one of the great epochs in the history of human progress (loud cheers); and if ever a spirit of prophecy has filled a man with something of a Divine enthusiasm it may well be that the man with whose name the system of the electric telegraph must ever be inseparably connected may have felt his heart throb with something almost of the supernatural when he realised that the great work had been achieved, that the demonstration had been reached, and that the future of the science had been assured (cheers). If he could have looked forward to those circumstances which are to us part of our everyday lives, he may well have been excused for such a shock to the nerves as hardly any seer of old can ever have encountered in peering into the dark future (applause). I venture to believe when we look back upon the progress of those fifty years we shall find in them the materials of a greater hope of the future of humanity than in almost any other record of any other period in the history of our race. I would remind you that the instrument which was employed by Wheatstone and Cooke displayed five needles, and that it was from the movements and combinations of those five needles that the whole of the alphabet was made up. Those five needles, we are told, were united by means of five copper wires laid in a groove in a triangular block of wood, and I am sure you will be interested to know that a piece of that block is in my hand at the present time (cheers), and well deserves to be preserved among the archives of science. Well, of course we are, with the experience of this half century, well aware that this system in the first instance was crude and imperfect. Demonstration had been arrived at, but perfection had to be reached. The difficulty that was immediately encountered in popularising the system was obviated by the development of the railway enterprise of this country, and the necessity which arose for rapid and certain communication along our lines of railway. And those of us who are in the habit of travelling by the different great lines of the kingdom may, I think, for a moment indulge themselves in the idea of what railway travelling would be if there was no electric telegraph (laughter and cheers). However, some time elapsed before the real development of telegraphy in this country began. The London and Blackwall Railway was, I believe, the first to utilise the system in a practical way. In 1844 the Government of Sir Robert Peel first conceived the idea of utilising the telegraph for other than railway purposes—at least, they were the first to realise how far it could be applied to the service of the State, and that year saw the establishment of a telegraph line, from Waterloo to Gosport, of four wires, of which two were to be utilised by the railway company and two by the Government, and that I think you may say constituted the first public recognition of the value of the electric telegraph (applause). In 1846 the first telegraph company was formed, the Electric Telegraph Company (cheers). In 1850 the first attempt was made to lay a submarine telegraph cable (cheers). A gutta percha wire without any metallic covering was laid between Dover and Calais in August of that year, and you will be interested to know that I have also here a portion of that cable, which was fished up by a ship in the Channel so recently as the year 1875. I am told that the first concessionaire of that cable is present here this evening (cheers). In 1851 a cable was laid in substitution of this gutta-percha cable, which was protected by iron wires and which was the commencement of a regular system of inter-communication between England and the Continent, and this cable, I believe, I am not wrong in associating with the name of one of those gentlemen who is happily still spared to be among us, and to whom I referred just now in connection with the last toast, I mean Mr. Crampton (cheers), and it must indeed be a great satisfaction to anyone who has been connected with great works of this sort to have lived, as Mr. Crampton has done, to witness their enormous development in the service of mankind. The first Atlantic cable was laid in 1858, and other companies arose during those years to compete with the first electric telegraph company, and multiplied throughout the length and breadth of England the agency of the telegraph. In 1870 the multiplication of the companies had become so great, and their competition, though in some respects advantageous to the public, was yet so imperfectly regulated by State requirements that the Government of the day determined to acquire the whole of their enterprises, and to place the telegraphs of the kingdom under the direction of the Post Office (cheers). Now, I should like to say one or two words with regard to the instruments of telegraphy. We are aware—and anyone who wishes for ocular inspection may satisfy himself—that the first telegraphic apparatus employed by Wheatstone and Cooke was one which required five wires through which to transmit their message. It was found gradually that two wires would suffice to forward a message, and after that the progress of science enabled the operators to depend upon one. But after a time it became ascertained that a wire could be used for sending messages in two directions, and after that time four messages came to be transmitted on a single wire, two in either direction, and, as I daresay most gentlemen who are present to-night are aware, at the present time a single wire is being used at the central telegraph station in such a manner as to admit of six messages being sent in one direction, or one in one direction and five in the other, or any other combination of six messages (cheers), and I think that those who perfected these wonderful operations may be thankful that they live in the reign of our present good Queen (cheers), because I am perfectly satisfied that if they had lived in the reign of good Queen Bess most of those gentlemen would have expiated their scientific offences by being burned at the stake (loud laughter). The first instrument was succeeded by the double needle, the double needle by the single needle, and all those systems were visual. Then came in the system of printing on a bit of paper. At first the signs representing the letters were embossed on a band. This was further improved by Prof. Hughes's printing instrument (cheers), by which the actual letters were printed in ink. Then came yet another, probably even more astounding development—the sounder instruments, by which messages are transmitted by sound without any record (applause). I venture to believe that that achievement has outstripped the wildest dreams of imagination. With regard to speed, that I think is also an interesting point. When the first electric telegraph was established the speed of transmission was from four to five words a minute on the five-needle instruments. In 1849 the average rate of transmission of a certain number of messages addressed to *The Times* newspaper was seventeen words a minute. The present pace of the electric telegraph between London and Dublin, where the Wheatstone automatic instrument is employed, amounts to 462 words a minute (cheers), and thus what was regarded as miraculous 50 years ago has multiplied a hundredfold in the course of half a century. Now, you may perhaps like to know, though it is rather descending from the higher walk of this great subject, the number of telegrams which were sent through the Post Office in the United Kingdom last year. The number was 51,500,000 (cheers)—that is to say 1,000,000 per week—and that number is steadily increasing; 41,000,000, or rather more than that number of these were inland messages, and of course a very great proportion of them were press messages I think you should realise the immense boon which the electric telegraph has bestowed upon the press. I gather from such information as I have been able to obtain that the rate of press messages, which, as everybody is aware, is very much less than the rates for other messages, is on the average not much more than 2d. per 100 words; and it is owing to these extraordinary facilities which are afforded by the Post Office to the transmission of press news that the whole of the United Kingdom is put in possession at its breakfast table every morning of everything which it is necessary or important for anybody to know, as well as of a great many things which are neither necessary nor important (laughter and cheers). I believe that I am not wrong in saying that the cost to the public revenue of this reduced rate to the press is not less than £200,000 a year, and that the newspapers of this country

Digitized by Google

practically receive a subsidy of £200,000 a year in order to enable them to assist in the diffusion of intelligence (applause). I imagine that the country is also satisfied that this should be so, and that there are very few people who would wish to abridge that privilege having regard to the enormous importance to all classes of the community of being placed at the earliest moment in possession of the fullest knowledge of what is going on (applause). But it is a fact that, owing to the recent reduction in the tariff of telegrams, the value of the telegram, on the average, to the State is now only 8d., whereas two years ago it was 1s. 1d., and before the State took over the telegraphs it amounted to as much as 2s. 2d. I think you may measure something of the enormous gain which the public has achieved by the acquisition by the State of the telegraph system when you look at these figures and reflect that the average price of a telegram at the present time is only about one-third of what it was only seventeen years ago (applause). I am saying this as if I were one of the public; but as Postmaster-General you must be aware that I have to regard this result with somewhat mixed feelings (laughter), and I am endeavouring, as far as I can, to denude myself of any official prepossession in putting before you from the popular side the advantages which you have obtained by the State employment of the telegraphs. But, gentlemen, I feel that I have already trespassed on your patience. I would only say that if you would wish to obtain further knowledge of this most interesting subject, put in the most terse and pregnant way, you cannot do better than study a paper communicated to the Society of Arts by my friend Mr. Preece (cheers), in which the details of this marvellous progress are set out concisely and perspicuously. But I do not like to sit down without reminding you that whereas a Jubilee is generally a time of retrospect—and, indeed, we have a retrospect which I have endeavoured to trace upon which we may look with more than pride and more than satisfaction—yet this moment of retrospect is only one of those in which a powerful and vigorous organisation draws its breath in order to enter upon a new career (loud cheers). Not only have we something to be proud of in the past, but I believe we shall have much more to be proud of in the future. This great agency, which seems to form the vital principle of this planet upon which we live, which has not only gone so far towards annihilating space, but which seems at the present time to be generating light and revolutionising motion, has all the future before it (cheers). Those who are enrolled in its service are probably the disciples of a new and absolutely beneficial dispensation, and with them rests the future in no small degree of the human race (applause), and the means of linking not merely ourselves to our distant colonies—and my noble friend who is beside me (Lord Onslow) reminds me how important is the connection between England and the younger Englands beyond the sea (cheers)—but by going forward in connecting the various races of mankind, by binding island to island and continent to continent, the telegraph is doing in its quiet, noiseless, and in its own unobtrusive way more than all the noisiest missionaries of peace and universal brotherhood have ever accomplished (applause). The names which I ask leave to couple with this toast are those of Mr. Edwin Clark, who is, as we know, one of the veterans in the service of the electric telegraph, and of Mr. John Pender (cheers), who has made our English science cosmopolitan, and last, but certainly not least, the name of Sir William Thomson (prolonged cheers), who, I am proud to think, as a humble member of the same university, has done more than any other person connected with that ancient seat of learning and science to maintain its high reputation as one of the pioneers of scientific thought. Gentlemen, with these three illustrious names I beg to couple this toast, and while thanking you for the patience with which you have listened to what I have ventured to say to you, I make bold to predict for this great science, in whose honour we are gathered together here to-night, another and much ampler Jubilee whenever the next half century enables it to take stock of the marvellous labours which it achieved for the benefit of the human race, for the development of human enlightenment, and for the propagation of universal peace (loud cheers).

The toast was enthusiastically drunk.

Mr. Edwin Clark, who was applauded on rising, in the course of his remarks (which were uttered in so low a tone that they were heard with extreme difficulty, and at times were totally inaudible) said he had been selected for the honour of responding for the past of telegraphy, but he should confine himself to allusions to that which came under his own observation whilst he was connected with the Electric Telegraph Company. The arts and sciences had always been very closely associated, and it was often difficult to say where the one ended and the other began. This was exemplified in the case of telegraphy, which began as a pure science, but had eventually become almost completely an art. Now, however, it was becoming a science again under the fostering care of the clever and energetic men who were engaged in combining theory with practice. Having referred to the fact that Cooke and Wheatstone were the originators of anything like practical telegraphy on a large scale, Mr. Clark said it was he who introduced Wheatstone to Robert Stephenson. Stephenson at once took up the subject of telegraphy, foreseeing its value and importance. He granted permission for the line which had been erected for experimental purposes between Euston and Camden Town to remain. The first use of the telegraph of any importance was made upon this line. There had been previous telegraphing, of course, and he was not saying that Wheatstone invented the telegraph; he was only stating that this was undoubtedly the beginning of the practical application of the telegraph. Mr. Stephenson having taken the matter up, for some years worked very assiduously for its development. In 1837, he (Mr. Clark) believed, he formed a company, which came out as the Electric Telegraph Company. He was associated with some very eminent men—with Whitworth, of Manchester, Ricardo, and others; they were capitalists, and they found the money and formed the Electric Telegraph Company in that way. In the years 1846-7-8 he (the speaker) was employed in the construction of the Britannia Bridge, and had nothing to do with the telegraph, but before he completed the bridge he was sent for to come to town in order that he might take charge of the Electric Telegraph Company, which was then working under very peculiar circumstances. He was told that the expenditure was very large, and that they were losing a sum of something like £50 or £60 a week. His instructions were to go into the matter carefully, and investigate the affairs of the Company, and see whether it would be better to reorganise it or to abandon the undertaking altogether. He knew very little indeed of the subject, for he was not an electrician. But the question which was brought to him for solution was this—there was a certain number of lines, a certain number of customers, and there were certain expenses; could these be modified and so apportioned that the undertaking could be made to pay its way? When he and his brother (who was associated with him in the inquiry) came to look into the affair, they found that very great economy could be effected in different ways. There was a great deal too much laboratory work going on at that time; there was nothing decided or known, no uniformity, the wires were of all sorts and sizes, and the materials generally were in a very precarious condition. The first thing was to get the instruments into proper workmanlike form, and to secure the proper insulation of the wires. The poles on which the line was suspended were of a very light character, were too small, in fact, and he brought down a number of excellent practical men from the Britannia Bridge to overhaul the whole concern. About this time he (the speaker) was engaged in negotiating with the whole of the railways with the idea of thoroughly working out the telegraph system. They were treated by the railway companies with very great liberality. They gave them rights of way, and even paid a portion of the expenses of laying the Telegraph Company's lines. They found it so important to themselves that it was worth their while to give it their assistance, and there was such a demand for the telegraph they could hardly execute the work fast enough. They laid down, generally speaking, a special line for the railway companies, and a special line for themselves, it being understood that they assisted each other with their respective wires. They had a clerk in almost the whole of the stations, who was partly paid by the railway companies, and partly by the Electric Telegraph Company, and whose duty it was to transmit the messages of the companies. That was the

Digitized by Google

beginning of the commercial success of the undertaking, and it was entirely attributable to the railway companies. About this time he was deputed by the North-Western Railway Company to examine the telegraph systems of Europe, and especially of Germany. From what he saw during that journey he recommended the adoption of a system which had now come into almost universal use, the block system (applause). Their instruments and their wires were at that time of a very elementary character, and they very seldom tested the lines for the reason that their testing instruments were not at all applicable for the purposes of durable telegraphy. But these matters were soon improved under the supervision of the excellent staff he had around him. There were associated with him Varley, his (the speaker's) brother and Mr. Preece (the latter of whom he was glad to have introduced to the service). These and others turned their attention to the improvement of the apparatus, and so many alterations were made that in a short time the company was placed on a good sound footing. Having briefly referred to the earlier investigations in regard to telegraphy, Mr. Clark concluded by referring to the work done in connection with submarine telegraphy by Mr. Jacob Brett, who was present at that gathering, but since whose first attempts were made wonderful progress had taken place (cheers).

Mr. JOHN PENDER, who on rising to respond on behalf of telegraphy in the present was loudly cheered, said: Mr. Raikes, my Lords and Gentlemen—You have heard to-night the very admirable speech of our president, and he has given you in a very concise form the progress of telegraphy during the last fifty years. He has told you of the little telegram from Euston to Camden Town, and of the anxieties which attended those first moments of the telegraph; and he has also told you that to-day there are over 50 millions of telegrams passing over the telegraph lines of this country. I have been asked to speak of the present of the telegraph. In these few words I tell you what land line telegraphy is and what it has achieved. My mission to-night is more to tell you what submarine telegraphy has done (applause.) Let it be remarked first that I do not speak as an electrician. I believe I am correct in saying that the majority of this company are electricians, but I am one of those few commercial men who at an early period of telegraphy saw that there was in it the promise of a beneficent instrument for the future progress of the world. I have gone into submarine telegraphy, not as an expert, but as one of those who have come forward and taken Science by the hand, and led it up to the glorious results which we have seen. Twenty years ago there were only something like 2,000 miles of submarine cables; now there are 115,000 miles, and it has cost something like £38,000,000 or £39,000,000 sterling to put that amount of telegraph cable to the bottom of the sea. There was a prophecy long ago that the earth was to be girded round in forty minutes. Why, we have got as much submarine telegraph cable as will go round the world five times, and we can send a message round the world in twenty minutes at the present moment. You ask me where does all this submarine telegraphy extend, and I would reply in those beautiful lines of the poet—

> "Far as the breeze can bear the billows' foam,
> Survey our Empire and behold our home!"

Wherever the British ship goes, or the British flag flies, there we have set the submarine telegraph, and at the present moment while I am speaking to you human thought is travelling like lightning to every part of the world. The future of that no man can tell. Of the 100,000,000 words which are now carried by submarine telegraphy nine-tenths are for commercial purposes. You can conceive the amount of progress and the amount of benefit to the human race which follow the facilities thus given to commerce. I might talk for a long period of the advantages which telegraphy has given to politics, to commerce, and to social interest; but I will only say this, that if the progress of the next fifty years is as great as the progress of the last twenty it will be the greatest marvel that has ever been known in this world (applause). I know the value of time, gentlemen; I have been taught that in telegraphy. I know there are many much more important speeches to follow, and therefore I will not detain you longer than this. When the history of these fifty years of Her Majesty's glorious reign is written telegraphy, and more especially submarine telegraphy, will be shown to have done more than anything else to federate the great colonies and the mother country, to spread civilisation throughout the world, and to make this great world of ours as near as possible one common country (cheers).

Sir WILLIAM THOMSON then rose to respond, and was greeted with an enthusiastic outburst of cheering. He said: Mr. Raikes, my Lords, and Gentlemen—It is with feelings of a very mixed character that I appear this evening to speak for my fellow workers in the great work of the last thirty years of ocean telegraphy. I understand that it is ocean telegraphy in respect of which you have done me the honour of allowing me to speak this evening, because in the earlier part of the development of the telegraph I had no part; I have only recollection. But I do feel that when the telegraph has been so important a bond for all the nations of the world that we ought to go even beyond our fifty years' Jubilee and think for a moment of the great names from other countries to whom the possibility of the Jubilee of the Electric Telegraph has been due—the great apostles of electrical science in France, Coulomb and Ampère (cheers). Ampère, whose work and whose discoveries constitute the foundation of the most important of modern telegraphic and electric instruments generally—Ampère, whose name has become Anglicised and is invariably used in measuring the currents which produce the electric light. Then Gauss and Weber, who made the first electric telegraph. Mr. Edwin Clark justly and fairly expressed himself just now when he said that the telegraph of Cooke and Wheatstone was the first practical working telegraph, but he knew that others had worked in that field before, and that it was the practical realisation of their work that we owe to our own great countrymen, of whose splendid works he has spoken so ably. The telegraph of Gauss and Weber, and the Munich telegraph of Steinheil, and the Steinheil key, which is the manipulating telegraph key of the present day—these were the elements of telegraphy. We justly rejoice that in England so much was made of the work of those grand pioneers in science. In America the race of practical work commenced almost simultaneously with our own in the splendid telegraph of Morse. In speaking of the telegraph we almost forget time and space, and I must go back to the previous work of Henry, who anticipated in some points some of the finest discoveries of Faraday, and laid a large part of the theory of current induction, which is at the very root of some of the most splendid realisations of modern electrical science, not merely for the electric telegraph, but for electric lighting. But I am reminded that my own position to-night is to speak of my fellow workers in ocean telegraphy, and in doing so I may say I have very mixed feelings. Most of them have gone away, few are here now, I am almost alone. By the work of 1857—a few years before the half of the Jubilee—the two brothers Edward and Charles Bright and Whitehouse—those three men, with Mr. Cyrus Field, had reduced to practice the brilliant dream of Cyrus Field to connect England and America by means of submarine telegraphy. Then there were the brothers Werner and William Siemens working in the same direction, and the great navigator Moriarty, who was out in the "Agamemnon" in 1857. I had the honour of being shipmates with him on the "Agamemnon." He navigated the "Agamemnon" in 1858. I was on the "Great Eastern," with Sir James Anderson as navigator. In 1865 and 1868 he picked up the cable, and again in 1866—in 1865, when it was broken, and in 1866, coming back a year after, in the same place, hitting upon it just a quarter of a mile away by splendid navigational powers. Canning and Clifford, Varley and Jenkin (who was my special partner), and who worked altogether for many years. I, alone, am here to speak for the three. Willoughby Smith, who did such fine work in 1865-6 in testing the cable, applying the newest developments of science, many of them his own inventions, to do what had never been done before, to test a submarine cable with the delicacy that was necessary under cir-

THE TELEGRAPH JUBILEE BANQUET.

Although the Jubilee Banquet in commemoration of the Fiftieth Anniversary of the ELECTRIC TELEGRAPH was presided over, as fittingly it should be, by the English Postmaster-General, the assembled guests were sufficiently representative and imperial to raise the event far above the level of a mere official or insular festivity. English citizens, however, as distinct from any English Government, have special cause for pride and congratulation on an occasion like the present. The ELECTRIC TELEGRAPH may be claimed, without much presumption, as their own invention; and as a working system it may be said to be almost literally their personal property. Still more flattering is the fact that in its broader and mightier aspects the ELECTRIC TELEGRAPH is the work of their unaided genius and indomitable perseverance. Other nations have their local telegraphs just as England has hers; but no people or nation can rob her sons of the distinction of having linked together in these days the widely separated families of the world, and put them on speaking terms with each other as brothers with brothers.

This is no mean achievement, and its greatness was fully appreciated by every speaker, conspicuously by the Chairman himself, who addressed the distinguished and historic gathering of telegraphic, engineering, and scientific representatives on Wednesday night. For, assuredly, the essential boon which mankind owes to the discovery of electric telegraphy is not to be seen in its adaptation to local and domestic uses, great indeed as these are, but in its application to the intercourse of nations one with another; and in the gradual effacement of those hostile barriers which are the natural consequence of ages of estrangement. We are not reckoning on the millenium; and we do not imagine that the ELECTRIC TELEGRAPH is going to insure universal peace and goodwill by its own unassisted magic. But we may humbly affirm that there is no single agency at present wielded by man that is tending so much towards that end, or that with such reasonable confidence may be predicted to bring it about in due time.

Of its material benefits we need not speak at any great length here, but it naturally suggested many eloquent eulogiums in the after dinner speeches. By increasing the agencies and facilities of commerce, the TELEGRAPH has enormously enlarged the productiveness of the earth, and widened the scope of human industry upon every corner of it. And it necessarily follows that as nations and peoples become more and more dependent on each other's well-being for the necessaries and luxuries of life which, but for the TELEGRAPH, could never be supplied, the more likely are they to forget their race prejudices, and to let their animosities be swallowed up in their material and social interests.

All this is certainly true of the nations remotely apart. Of those nearer together it is sometimes said that their quarrels are fomented by electricity, and that telegraphy is responsible for keeping the European families at fever heat. Probably the truth is that the telegraph is far less to blame than the incendiaries who abuse it for their own selfish aims. At any rate it may be urged on the other side that if the electric message is quick to provoke it is not less swift to appease. Many instances might be cited of the telegraph playing the part of peacemaker when nothing but its instrumentality could have averted a pitiless war. All wars, it has been truly said, are the result of misunderstanding; and for prompt agreement with "thine adversary" there is nothing to equal the telegraph.

On these higher functions of the ELECTRIC TELEGRAPH we dwell with hopefulness and pride to-day. Those narrow minded reformers who magnify what may be called the parochial advantages of the telegraph, to the disparagement, or at all events the neglect of, its cosmopolitan services, might learn a useful lesson from the speeches of the men whose foresight and energy have established telegraphy over every part of the habitable globe. Their conception of the telegraph's mission was, and is, a far loftier one. But, taking merely insular and patriotic grounds, it is clear that the British Empire has most to gain by enterprises of this kind; and that her international and intercolonial cable systems are of the deepest national concern to us. Compared with the security, the efficiency, and the financial prosperity of these lines, the welfare of our inland telegraph system is an insignificant matter indeed. Only when the distances to be traversed are considerable, and when the interests involved are momentous, is the true value of the telegraph impressed upon us. Within narrower limits it may be misused, or abused, or even dispensed with like any other luxury. But long distance telegraphy over lands and seas has become an indispensable instrument of England's preponderance as an imperial and mercantile power. Twenty years of submarine telegraphy, as was truly said on Wednesday night, have done more to make this nation rich and prosperous, more to make her

Digitized by Google

people well fed and well clad, than all the political nostrums which parliamentary ingenuity has concocted during a century. The JUBILEE of the ELECTRIC TELEGRAPH will not have been celebrated in vain if only this important fact is impressed upon the public mind, and upon the minds of statesmen into whose hands are committed the destinies of this great empire.

(Continued from page 247.)

cumstances so peculiar, so utterly new. I am exceedingly sorry he is not with us this evening. I hope we shall see him many times more, upon some such occasions as this, and that he will soon recover from his temporary illness. But I can never forget that we scientists alone could not have done what has been done. I well remember the dead period of eight years, the middle of which was just the middle of our Jubilee that we are celebrating to-night—the years from 1857 to 1866. We were on our backs; we could do nothing in science; the cable had been laid—it proved to be a success; it had delivered messages—a message passed from the President of the United States to Her Majesty the Queen, and was answered by a gracious message from the Queen, and an important message countermanded the return of two regiments from Canada to England in order to go to India to quell the Mutiny—the countermanding of the return from Canada was done by the Atlantic cable of 1858. The Mutiny had happily come to an end, their presence at the end of the diameter of the earth, or pretty nearly so, was not needed, and the Atlantic cable of 1858 conveyed the intelligence to them that they might remain in Canada. The cable failed. I do not remember at present how much money was spent upon it—half a million, I believe—and science could do no more. To two men, I believe, is due the existence of the 1865 cable, and all the consequences that followed from the 1865 66 cable—John Pender and Cyrus Field (applause). With American spring, life, and energy Cyrus Field flashed across the Atlantic, not by wire, though, to our slow minds, it almost seemed so. He was here trying to get up an undertaking somehow or other, trying to induce English capitalists and scientific men to join together. But one man, Mr. Pender, was steadfast to the work. He was a director in 1858 of the Atlantic Telegraph Company. He, with some of his colleagues, remained on, and with Cyrus Field persevered until the successful undertaking of 1865. I call it successful, because it was really a successful undertaking, although the cable was only half laid. It led, with further tremendous effort and self-sacrifice on the part of those devoted men, and others who joined them, to the great and enduring success of 1866. But I am asked to speak of the present time of telegraphy, and not merely of submarine telegraphy, and I must remember that there are other things besides ocean telegraphs. We have our land telegraphs, of which you, Sir, have spoken. You have told us how splendidly the land telegraphs are worked, you have pointed out how admirably, under the influence of the Government system, the application of science to telegraphy has been developed. I think you may feel proud, Sir, in knowing that under Government management within these last seventeen years the applications of science to telegraphy have not stood still, but, on the contrary, have been pushed forward with every possible energy, and with the most marvellous success (applause). You have told us that the rate of working between Dublin and London has reached 460 words per minute, I think we may say 500 words per minute, and that is ten times what it was ten years ago. That is something for a Government Department to be proud of; and, for a Government, I must say there is some little political importance in the fact that Dublin can now communicate its requests, its complaints, and its gratitudes (laughter) to London at the rate of 500 words per minute. It seems to me an ample demonstration of the utter scientific absurdity of any sentimental need for a separate Parliament in Ireland (laughter and applause). I should have failed in my duty in speaking for science if I had omitted to point out this, which seems to me a great contribution of science to the political welfare of the world (applause).

The Right Hon. Sir LYON PLAYFAIR, M.P., who was loudly cheered, said: Mr. Raikes, my Lords, and Gentlemen—The toast which I have been asked to propose to you is that of "The Scientific Societies." I am sure that is a toast which you will all welcome here. There is some difference between the societies of the country and the peculiar habitudes of my friend who has just spoken. He is a remarkable example of a man from whom science and invention come from every alternate pore of his body. He is sometimes scientific, he is sometimes inventive; but the scientific societies do not profess invention. They profess to lay down the laws of science and to advance natural knowledge; and men who have contributed to advance natural knowledge like Œrsted, Faraday, Ampère, and others, are as much the discoverers of the electric telegraph as if they had themselves actually aided in the invention; because the duty of the scientific societies is to cultivate the tree of knowledge (applause). The tree of knowledge is one of slow growth, but in its time it produces the fruit of industrial invention. Those industrial inventions often—generally do—come by slow degrees, and it is very difficult often to say who is the first and true inventor of any particular contribution to industry. It is very rare—indeed, it is never the case—that a great invention which changes the face of society comes suddenly to the world, as Minerva came out of the brain of Jupiter, panoplied and full armoured. But recollect that even Jupiter could not do this till he swallowed the mother of Minerva, Metis, in the first month of her gestation, and then the gestation took a prodigious time, and afterwards there was a remarkable demonstration of Minerva coming out panoplied and full armoured. Now this is what inventors do. After science has gone through a proper process of gestation in their bodies, then come out their inventions slowly and by degrees, so much so that even in the case of a great invention like the steam engine, which is the only thing comparable with the electric telegraph in the influence it has had on the progress of the world, one of the highest courts of justice in this realm has decided, after reviewing all the steps in the advancement of the steam engine, that Watt contributed nothing at all towards it (laughter). It is the same with regard to telegraphy. One does not know when the electric telegraph was first invented. There was one little incident that I may mention. Many years ago I was dining at the mess of the Artillery, at Woolwich, and Prof. Wheatstone was one of the guests. I forget what the toast was, but it was something connected with his discoveries in electricity, and I described him in my speech as the discoverer of the electric telegraph. At that time Wheatstone and I lived within a few doors of each other, he on one side of Hampstead Bridge and I immediately at the other, and we always went home together, and he censured me for my foolish speech. He said that he was not the discoverer of the electric telegraph—that Œrsted and Faraday were its true discoverers, for it was from their discoveries that electric telegraphy originated. He had admitted that there had been many experiments in telegraphy before his day, but he claimed with pride that he had done considerable things for the practical promotion of telegraphy, and for the instruments which he invented in order to promote them. Now, the scientific societies to which I ask you to drink have for their duty the advancement of natural knowledge. Wheatstone himself was more proud in advancing natural knowledge than he was in the advancement of telegraphy, because he knew that it was by laying the foundation of science on a sound and firm basis that we are able to make inventions and applications of that science which does so much for humanity (applause). It is natural that we are struck in telegraphy with the almost practical annihilation of time and space. That strikes our imagination, but what telegraphy has done for the world is incalculable not only in adding largely to the resources of Government, but in having profoundly changed the whole practice of commerce all over the world (hear, hear). Capital which was formerly used in one way has now to find completely different outlets for its utility. The system of exchange

THE TELEGRAPH JUBILEE BANQUET.

Although the Jubilee Banquet in commemoration of the Fiftieth Anniversary of the ELECTRIC TELEGRAPH was presided over, as fittingly it should be, by the English Postmaster-General, the assembled guests were sufficiently representative and imperial to raise the event far above the level of a mere official or insular festivity. English citizens, however, as distinct from any English Government, have special cause for pride and congratulation on an occasion like the present. The ELECTRIC TELEGRAPH may be claimed, without much presumption, as their own invention; and as a working system it may be said to be almost literally their personal property. Still more flattering is the fact that in its broader and mightier aspects the ELECTRIC TELEGRAPH is the work of their unaided genius and indomitable perseverance. Other nations have their local telegraphs just as England has hers; but no people or nation can rob her sons of the distinction of having linked together in these days the widely separated families of the world, and put them on speaking terms with each other as brothers with brothers.

This is no mean achievement, and its greatness was fully appreciated by every speaker, conspicuously by the Chairman himself, who addressed the distinguished and historic gathering of telegraphic, engineering, and scientific representatives on Wednesday night. For, assuredly, the essential boon which mankind owes to the discovery of electric telegraphy is not to be seen in its adaptation to local and domestic uses, great indeed as these are, but in its application to the intercourse of nations one with another; and in the gradual effacement of those hostile barriers which are the natural consequence of ages of estrangement. We are not reckoning on the millenium; and we do not imagine that the ELECTRIC TELEGRAPH is going to insure universal peace and goodwill by its own unassisted magic. But we may humbly affirm that there is no single agency at present wielded by man that is tending so much towards that end, or that with such reasonable confidence may be predicted to bring it about in due time.

Of its material benefits we need not speak at any great length here, but it naturally suggested many eloquent eulogiums in the after dinner speeches. By increasing the agencies and facilities of commerce, the TELEGRAPH has enormously enlarged the productiveness of the earth, and widened the scope of human industry upon every corner of it. And it necessarily follows that as nations and peoples become more and more dependent on each other's well-being for the necessaries and luxuries of life which, but for the TELEGRAPH, could never be supplied, the more likely are they to forget their race prejudices, and to let their animosities be swallowed up in their material and social interests.

All this is certainly true of the nations remotely apart. Of those nearer together it is sometimes said that their quarrels are fomented by electricity, and that telegraphy is responsible for keeping the European families at fever heat. Probably the truth is that the telegraph is far less to blame than the incendiaries who abuse it for their own selfish aims. At any rate it may be urged on the other side that if the electric message is quick to provoke it is not less swift to appease. Many instances might be cited of the telegraph playing the part of peacemaker when nothing but its instrumentality could have averted a pitiless war. All wars, it has been truly said, are the result of misunderstanding; and for prompt agreement with "thine adversary" there is nothing to equal the telegraph.

On these higher functions of the ELECTRIC TELEGRAPH we dwell with hopefulness and pride to-day. Those narrow minded reformers who magnify what may be called the parochial advantages of the telegraph, to the disparagement, or at all events the neglect of, its cosmopolitan services, might learn a useful lesson from the speeches of the men whose foresight and energy have established telegraphy over every part of the habitable globe. Their conception of the telegraph's mission was, and is, a far loftier one. But, taking merely insular and patriotic grounds, it is clear that the British Empire has most to gain by enterprises of this kind; and that her international and intercolonial cable systems are of the deepest national concern to us. Compared with the security, the efficiency, and the financial prosperity of these lines, the welfare of our inland telegraph system is an insignificant matter indeed. Only when the distances to be traversed are considerable, and when the interests involved are momentous, is the true value of the telegraph impressed upon us. Within narrower limits it may be misused, or abused, or even dispensed with like any other luxury. But long distance telegraphy over lands and seas has become an indispensable instrument of England's preponderance as an imperial and mercantile power. cumstances so peculiar, so utterly new. I am exceedingly sorry he is not with us this evening. I hope we shall see him many times more, upon some such occasions as this, and that he will soon recover from his temporary illness. But I can never forget that we scientists alone could not have done what has been done. I well remember the dead period of eight years, the middle of which was just the middle of our Jubilee that we are celebrating to-night—the years from 1857 to 1866. We were on our backs; we could do nothing in science; the cable had been laid—it proved to be a success; it had delivered messages—a message passed from the President of the United States to Her Majesty the Queen, and was answered by a gracious message from the Queen, and an important message countermanded the return of two regiments from Canada to England in order to go to India to quell the Mutiny—the countermanding of the return from Canada was done by the Atlantic cable of 1858. The Mutiny had happily come to an end, their presence at the end of the diameter of the earth, or pretty nearly so, was not needed, and the Atlantic cable of 1858 conveyed the intelligence to them that they might remain in Canada. The cable failed. I do not remember at present how much money was spent upon it—half a million, I believe—and science could do no more. To two men, I believe, is due the existence of the 1865 cable, and all the consequences that followed from the 1865 66 cable—John Pender and Cyrus Field (applause). With American spring, life, and energy Cyrus Field flashed across the Atlantic, not by wire, though, to our slow minds, it almost seemed so. He was here trying to get up an undertaking somehow or other, trying to induce English capitalists and scientific men to join together. But one man, Mr. Pender, was steadfast to the work. He was a director in 1858 of the Atlantic Telegraph Company. He, with some of his colleagues, remained on, and with Cyrus Field persevered until the successful undertaking of 1865. I call it successful, because it was really a successful undertaking, although the cable was only half laid. It led, with further tremendous effort and self sacrifice on the part of those devoted men, and others who joined them, to the great and enduring success of 1866. But I am asked to speak of the present time of telegraphy, and not merely of submarine telegraphy, and I must remember that there are other things besides ocean telegraphs. We have our land telegraphs, of which you, Sir, have spoken. You have told us how splendidly the land telegraphs are worked, you have pointed out how admirably, under the influence of the Government system, the application of science to telegraphy has been developed. I think you may feel proud, Sir, in knowing that under Government management within these last seventeen years the applications of science to telegraphy have not stood still, but, on the contrary, have been pushed forward with every possible energy, and with the most marvellous success (applause). You have told us that the rate of working between Dublin and London has reached 460 words per minute, I think we may say 500 words per minute, and that is ten times what it was ten years ago. That is something for a Government Department to be proud of; and, for a Government, I must say there is some little political importance in the fact that Dublin can now communicate its requests, its complaints, and its gratitudes (laughter) to London at the rate of 500 words per minute. It seems to me an ample demonstration of the utter scientific absurdity of any sentimental need for a separate Parliament in Ireland (laughter and applause). I should have failed in my duty in speaking for science if I had omitted to point out this, which seems to me a great contribution of science to the political welfare of the world (applause).

The Right Hon. Sir LYON PLAYFAIR, M.P., who was loudly cheered, said: Mr. Raikes, my Lords, and Gentlemen—The toast which I have been asked to propose to you is that of "The Scientific Societies." I am sure that is a toast which you will all welcome here. There is some difference between the societies of the country and the peculiar habitudes of my friend who has just spoken. He is a remarkable example of a man from whom science and invention come from every alternate pore of his body. He is sometimes scientific, he is sometimes inventive; but the scientific societies do not profess invention. They profess to lay down the laws of science and to advance natural knowledge; and men who have contributed to advance natural knowledge like Œrsted, Faraday, Ampère, and others, are as much the discoverers of the electric telegraph as if they had themselves actually aided in the invention; because the duty of the scientific societies is to cultivate the tree of knowledge (applause). The tree of knowledge is one of slow growth, but in its time it produces the fruit of industrial invention. Those industrial inventions often—generally do—come by slow degrees, and it is very difficult often to say who is the first and true inventor of any particular contribution to industry. It is very rare—indeed, it is never the case—that a great invention which changes the face of society comes suddenly to the world, as Minerva came out of the brain of Jupiter, panoplied and full armoured. But recollect that even Jupiter could not do this till he swallowed the mother of Minerva, Metis, in the first month of her gestation, and then the gestation took a prodigious time, and afterwards there was a remarkable demonstration of Minerva coming out panoplied and full armoured. Now this is what inventors do. After science has gone through a proper process of gestation in their bodies, then come out their inventions slowly and by degrees, so much so that even in the case of a great invention like the steam engine, which is the only thing comparable with the electric telegraph in the influence it has had on the progress of the world, one of the highest courts of justice in this realm has decided, after reviewing all the steps in the advancement of the steam engine, that Watt contributed nothing at all towards it (laughter). It is the same with regard to telegraphy. One does not know when the electric telegraph was first invented. There was one little incident that I may mention. Many years ago I was dining at the mess of the Artillery, at Woolwich, and Prof. Wheatstone was one of the guests. I forget what the toast was, but it was something connected with his discoveries in electricity, and I described him in my speech as the discoverer of the electric telegraph. At that time Wheatstone and I lived within a few doors of each other, he on one side of Hampstead Bridge and I immediately at the other, and we always went home together, and he censured me for my foolish speech. He said that he was not the discoverer of the electric telegraph—that Œrsted and Faraday were its true discoverers, for it was from their discoveries that electric telegraphy originated. He had admitted that there had been many experiments in telegraphy before his day, but he claimed with pride that he had done considerable things for the practical promotion of telegraphy, and for the instruments which he invented in order to promote them. Now, the scientific societies to which I ask you to drink have for their duty the advancement of natural knowledge. Wheatstone himself was more proud in advancing natural knowledge than he was in the advancement of telegraphy, because he knew that it was by laying the foundation of science on a sound and firm basis that we are able to make inventions and applications of that science which does so much for humanity (applause). It is natural that we are struck in telegraphy with the almost practical annihilation of time and space. That strikes our imagination, but what telegraphy has done for the world is incalculable not only in adding largely to the resources of Government, but in having profoundly changed the whole practice of commerce all over the world (hear, hear). Capital which was formerly used in one way has now to find completely different outlets for its utility. The system of exchange

Digitized by Google

has been entirely altered, and the sons of merchants of fifty years ago no longer carry on their business by any of the traditions of their fathers. The whole system of commerce and Government has been altered by telegraphy. Now then the lesson—and it is the last thing I want to say—the lesson which telegraphy teaches us is this, that while we should rejoice in inventions we should never forget that science is the mother of invention, and that we should sympathise with every effort to promote the advance of natural knowledge. I am sure it is not necessary here to answer any of those stupid questions which forty or fifty years ago were asked of scientific men. "*Cui bono?* What is the use of your abstract discovery? It has no relation to the utilities of life." You recollect how Faraday answered that by asking another question. When somebody asked him what was the use of some abstract discovery he had made he replied by saying, "What is the use of a baby?" (cheers) But round that baby are all the hopes and all the future aspirations of the parents. It contains the potentiality of good and evil, and even the State interferes on its behalf by bringing in legislation to make it a good and useful citizen. Therefore we should, in regard to all discoveries, however unimportant they seem, do everything to promote their growth and to promote the growth of natural knowledge throughout scientific societies, not only in this country, but all over the world, and therefore I ask you to drink this toast, and I beg to join with it the name of one of the most distinguished scientific men in this kingdom, Prof. Stokes, the President of the Royal Society; and also the name of Dr. Gladstone (cheers).

The toast having been cordially drunk,

Prof. STOKES said: Mr. Raikes, my Lords, and Gentlemen—Considering the nature of the present occasion it might, perhaps, be expected that I should say something of the practical application of scientific studies to the ordinary purposes of life; but I am sure it will be thought unnecessary that I should say anything on that topic. Every electrician present, of whom there are so many, must know that the practical applications of electricity could not be what they are were it not for the investigations of scientific men—of those who perhaps have studied electricity from a purely scientific point of view. Therefore, in the few words with which alone I intend at this late hour of the evening to trouble you, I propose rather to refer to the reciprocal benefit which the study of abstract science has received from the labours of those who have applied science to the wants of life. Scientific men know well how fascinating is the pursuit of science. Some have even gone so far as to consider that it would be polluted, if I may so speak, by being applied practically. An eminent foreign mathematician delighted in the theory of numbers because one could not conceive that it could have any practical application. An eminent English mathematician I heard express a somewhat similar sentiment, and I dare say Sir William Thomson may remember it—there were three of us present on that occasion. All honour be to those who are so immersed, if I may so speak, in abstract science that they disregard and even dislike its application. They pursue science with all the more zest, they pursue it in directions which possibly otherwise it might not have been possible to follow out, and possibly in the end their own investigations may admit applications which they never dreamt of. But for my own part my tastes do not quite lie in that direction. I like to see science connected with applications thereof, no matter to what purpose (hear, hear), and I think that my friend, Sir W. Thomson, has tastes similar to my own in that respect. Now, when we apply abstract science to physical subjects we are not only enabled to investigate natural phenomena in a manner which could not otherwise be done, but the study reacts on the most abstract parts of science and enables us sometimes to see as if it were by intuition truths of of an abstract nature, such as, for example, propositions in pure mathematics, which we, perhaps, should never have arrived at if we had not viewed them through the spectacles, so to speak, of their physical application. But that is not all. When science comes to be applied to the wants of life scientific men are placed by the practical men in the condition of making experiments which oftentimes would otherwise be impossible. When science comes to be applied to commerce it then becomes possible to construct instruments on a scale the expensiveness of which would be utterly prohibitory to the scientific man (applause); but, when these instruments are constructed, it may be for commercial purposes, the scientific man on his part is able by the favour of those who have constructed them, or by those for whom they have been constructed, to make experiments with them, which oftentimes are of great interest from a purely scientific point of view (hear, hear). I remember the interest with which I read some of the experiments which Faraday made by means of a cable which had been constructed for crossing the Atlantic, though as yet it lay in its tank. The theory of this is now well known, and my friend on my left (Sir William Thomson) has been one of the foremost in investigating it; but then the subject was scientifically in its infancy, and I do not know how far or how fast it might have progressed had it not been for the facilities for scientific investigations which have been placed in the hands of pure scientists by those who constructed their instruments for the purposes of commerce and the general objects of life. Gentlemen, at this late hour I will no longer detain you, but thank you for the honour you have done me (cheers).

Dr. GLADSTONE, responding on behalf of the Royal Institution, said he felt it was no small honour to take part in the proceedings of so interesting a gathering. He was sincerely sorry that Sir Frederick Bramwell, who was to have responded to the toast, was unable to be present to delight and instruct them with his genial wit and wisdom. As far as the Royal Institution was concerned, of course it was not the Royal Institution which had been spoken to in the toast, but rather those members connected with it in reference to telegraphy and electrical science. At the Royal Institution there were not merely memories binding them to all those who had passed away, but they had also many relics. They preserved the log books of Davy, Faraday, and others, and not only that, but there were a great number of pieces of wire, sealing wax, and card, all damaged, and many other things which Faraday used to delight to work with, and to carry out the first experiments which were suggested by the ideas that were working in his brain, and these were preserved as germs of some of these great discoveries. They had there, for instance, a small range of soft iron with iron wire twisted round it, insulated by calico, and tied up with string, from which he obtained his first electric effects from magnetism (applause). He mentioned these things because they had already had brought before them in one form and another many ways in which the electric telegraph had been traced back to its original germs, and here he wanted to point out one of those germs connected with telegraphy. Those relics preserved at the Royal Institution were only worth originally a few pence or shillings; how different the monster wealth which had now become the capital of those great enterprises! As far as the Royal Institution was concerned, its connection with the electric telegraph was to a certain extent not direct, and yet it was very real. Sir Humphrey Davy worked there of course largely with galvanic electricity, but he belonged to the pre-telegraphic era. Faraday himself commenced to work early in these matters, and continued to try and image in his own mind what was taking place in these phenomena, and he always marvelled at the results arrived at even when he knew more than anybody else about what took place. He seemed to have been constantly wrapped in his experiments, and his enthusiasm took him forward from discovery to discovery, all tending to show connections between the different branches of electricity and the various forces with which they were acquainted. It had already been remarked by Sir Lyon Playfair that Faraday was a discoverer, and did not care much for invention. There were some, like Wheatstone and Sir William Thomson, who were distinguished in both departments, but it was not given to very many to be so. Faraday gave the whole of his life to investigation and development; but while he did that he also encouraged those who were working in practical applications. It was an important point with him that the glories of science should conduce to the benefit of man. They knew his influence with Sir Charles Wheatstone was very great, and he got him

Digitized by Google

into the dark chambers at the Royal Institution, and talked to him about his investigations, and in the theatre brought before him some of those experiments which were afterwards performed with so much success in public. In one way and another Faraday had to do with the industrial applications of electricity as well as with scientific discovery. One of the very earliest experiments of Faraday that led to some of his discoveries was in relation to Ampère's experiments. They had a record of how delighted he was when he found that he was able to produce not only the effect of the wire revolving round the magnet but of the magnet revolving round the wire, and how he revolved round the whole of his experiments and declared he would do no more work on that day (applause). In another reminiscence they found him thinking of what could be taking place in the dielectrics, and getting out what was retarding the force, what was enabling the force to propagate, until at last he conceived the idea of specific inductive capacity. They knew how that was taken up by Sir William Thomson and others in various ways, and led to a number of other interesting discoveries (applause). Those were the trophies of early electrical discovery; but electrical discovery would have been of very little use if it had not been that others came in and took up those discoveries and applied them. They had the combination of the purely scientific man with the practical man, and these two going together with slow, careful, conscientious investigation, followed by the energetic carrying out of the discovery in a form which benefited mankind (applause).

Mr. SHAW-LEFEVRE, M.P., said: Mr. Raikes, my Lords and Gentlemen—I feel highly honoured by being called upon to propose to you the next toast, and I shall best show my appreciation of that honour by ruthlessly cutting down by three-fourths what I had intended to say to you, for at this late hour of the night you are doubtless anxious to get away. I am, gentlemen, I am sorry to say, just old enough to recollect, if not the birth of telegraphy, at all events its earliest infancy, for I have a vivid recollection of having been taken by my father, when a boy, to the house of a friend, where Prof. Wheatstone set up a model of his invention, and where it was explained to us by the two great inventors—namely, Prof. Wheatstone himself and Faraday. It impressed itself on my mind the more because, although I understood very little about it, I recollect my father saying that I had met two great men on that occasion, the authors of an invention the nature of which nobody could then understand. When I was a boy at Eton I recollect well the extension of the telegraph from London to Slough, and of an incident of which you are all aware, the arrest of Towell, which I believe brought the telegraph more into notice than anything at that time. It might have been expected that the authorities at Eton, seeing a great invention of this kind brought to their door, might have been desirous of explaining it to the boys of the school, and might have been drawn out of their deep slumber of ages, and done something for the scientific education of the boys then at Eton. But no thought of that kind ever entered into their minds, and the only notice taken of it at that time was that they set it for the subject of some Greek verses (laughter), and all the boys of my class had to rack their brains to write some iambics on a subject of which we knew nothing, and to bring it into connection with the mythology of the ancients, of which we knew a good deal. I refer to this for the purpose of showing you how little science was promoted at our public schools. I am glad to say that things have been changed since (cheers); but much has to be done in this direction, and there cannot be a doubt that, if this country is to hold its own in the great industrial competition, it must give a greater place to science in our schools and equalise the endowments between the classical and scientific studies (cheers), and it is only by doing that, I am persuaded, that we can hold our own. We have been proud of the past in respect of science. Sir Lyon Playfair has already spoken of that branch of scientific men who devote themselves to pure science. It is my duty to propose the toast of that class of scientific men who devote themselves to that part of science connected with the industries and commerce of this country (applause), to the mutual advantage of both; for if science has multiplied the commerce and industry of this country a hundred fold, it owes it to men who have devoted themselves to applied science, and many discoveries could not have been made if it had not been for the important impetus which the industry of the country had applied to them (applause). I doubt whether there is any country in the world where there is a more devoted band of scientific men to the branch I speak of (hear, hear), and in the two great societies, the Civil Engineers, and that concerned with telegraph engineering, we have two bodies of men who have conferred inestimable benefits on the country. The one has supplied the country with all its railways, and has carried the capital of England to every part of the world, and has constructed railways in India, and given the model of them to many other parts of the world. I need hardly say that the telegraph engineers have given to England a monopoly of submarine telegraphy throughout the world (cheers) which has been an enormous advantage to the country. I beg, therefore, to conclude by proposing "The Societies Representing Applied Science," and to couple with it the names of Mr. Bruce and Mr. Latimer Clark (cheers).

The toast was duly honoured.

Mr. BRUCE, in responding, said: My Lords and Gentlemen—There is manifest fitness in the arrangement by which the recognition of science takes precedence to-night of the recognition of the application of science. It is in the latter and humbler walk that the engineer may be said to tread. The student of pure science follows it for its own sake. He dives into the mysteries of Nature from the pure love of making it reveal to man something which he did not know before (hear, hear)—a lover of seeking rewarded by the satisfaction of finding. The engineer, on the other hand, is the humble attendant upon the man of science, and when this man of pure science reveals some new law, then it is clearly our duty to try and find out some means by which that addition to the world's knowledge may be made to add to the world's wealth and happiness in things material. I think, gentlemen, we also have been very successful in the past in this department of the world's work, and we need no other testimony with regard to that than the position of telegraphy to-day, with the marvellous changes which it has wrought in the social life and in the commerce of the world, as we have heard early this evening from so many speakers. In fact, there is not the least doubt of it that the most marked feature of the reign of our Most Gracious Queen, and that by which it will be distinguished all down the ages, is both the application of science upon sea and land, in order to ameliorate and lessen human labour and to make the powers of Nature work for man (applause). That you have coupled to-night with this beneficent enterprise the Institution of Civil Engineers, which I have the honour to represent, I heartily thank you. We have faith in our mission because, although the instrument which the engineer may be said in the main to use for the advancement of human progress is iron, still we think we see in the forecast of the future indications that the golden age is before and not behind us (applause).

Mr. LATIMER CLARK, who was received with cordial applause, also responded. He said: My name is associated with that of the President of the Institute of Civil Engineers because I am intimately acquainted with the history and development of the Society of Telegraph-Engineers, and because the subject which the telegraph engineers have taken to themselves is one which is specially interesting in connection with the present Jubilee. Now the society, as most of us know, began in the year 1872, and was founded by the late Col. Sir Francis Bolton, who we all deplore, and by another gentleman, who I am happy to say is with us to-night, Major-General Webber (cheers). The society has had a career of great prosperity and success. It has increased in numbers, in popularity, and in usefulness day by day, and I am happy to add that its finances are in a sound and satisfactory condition. But it is not by success and prosperity that we are to measure its importance. We owe our importance on the present occasion to the fact that we are connected with the science of electricity, and that we deal with a fluid or power which has the most wonderful properties. These properties are little understood and little known, but the importance of their application is obvious to all mankind.

Digitized by Google

In the first place, electricity is marked above all things by its wonderful power of propagation. It has a mysterious connection with all the other forces of Nature—energy, light, and heat. There is a charming simplicity about its laws which has engaged the attention of all the scientific men of the period. We produce results which are apparently marvellous in the eyes of mankind; we produce effects which are most brilliant. We are able to utilise the powers of this wondrous fluid or power for almost all the purposes of life; and, lastly, there lies before us obviously an unknown future, but one which must be of great importance to mankind. It is a fact that it is this peculiar agent which gives our society the importance which I feel it possesses. It is natural that the society should have lost many of its members. I have to deplore the loss of some men whose names are on the pages of history. I need only allude to such names as those of Cooke, Wheatstone, and Morse, and other men equally well known to you—Ronalds; we cannot name Faraday as one of the members, but he is one of those who have gone before in this matter. I am happy to feel that we have here to-day other names which are equally splendid. We have with us this evening one man who, by a singular fatality, is not a member of the society, but who certainly ought to be. We have with us this evening Mr. Jacob Brett (cheers). He undoubtedly is the father of submarine telegraphy. We have heard stated with great eloquence this evening the results achieved by submarine telegraphy; we heard from Mr. Pender the wondrous extent to which it has been carried; we have heard from Sir William Thomson, with his usual eloquence, the marvels of the Atlantic telegraph; we know that the highest honours have been deservedly bestowed upon those who were connected with it. But by some accident we have forgotten that before the Atlantic telegraph existed there were such things as submarine telegraphs, and that submarine telegraphs had arrived practically at full perfection, and the men who had brought it to that perfection were Mr. Jacob Brett and his brother, associated with others who deserved equal honour and credit (cheers). The Atlantic telegraph itself was brought into existence through the efforts of the brothers Brett, and I think we do an injustice to the science of electricity and to the art of submarine telegraphy when we forget them in the history of the subject. There can be no doubt that some seven years before the Atlantic telegraph they had successfully laid and put into working order a system of telegraphs which was in every respect the type of all the telegraphs of the present day; therefore, I say we are doing an injustice if we do not remember that these men were the real pioneers of submarine telegraphy (cheers)—if we do not remember also that when the centenary of submarine telegraphy comes forward in 1950, the names of the Bretts must be prominent as the originators of submarine enterprise (applause). I had forgotten the name of Siemens; I do not know why, for I intended to refer to it. No greater name will go down on the roll of famous scientific men (applause). There is one other subject I would mention to you. In the circumstances of life I have been entrusted with a number of valuable documents connected with the history of electric telegraphs. I was entrusted by Sir William Cooke with all his private letters and papers on the subject; I have have entrusted by Mr. Jacob Brett with all the interesting documents which he possessed connected with the establishment of submarine telegraphy; I was entrusted by Prof. Morse with some of the earliest specimens of his inventions connected with the electric telegraph, signed with his autograph. I feel that I have arrived at a period of life when it is prudent that I should relinquish that charge, and I now desire to state publicly my wish to hand those documents over to the custody of the Society of Telegraph-Engineers (cheers). I might now have ended by merely thanking you in the name of the Society of Telegraph-Engineers for the very kind manner in which you have received the toast; but the toast is that of the societies which are connected with applied science, and when I think of that toast I am emboldened by the patience with which you have listened to me to make one other remark, which shall be a very brief one. I feel that we, as the representatives of applied science, have been somewhat neglected by the world. I feel that the politicians, some of whom have honoured us by coming here this evening, have very much neglected us. I do not allude to honours, for we shall be very well content with the position of things in that regard; but I feel that they have robbed us of much of our credit, and that the great effects of the Jubilee which we are now assembled to commemorate have been due to the agency of applied sciences. I do feel that politicians have been permitted to claim for themselves the credit for the wondrous benefits civilisation has received from the efforts of applied science. We hear that so many shillings have been taken off a quarter of wheat, we hear that all the prosperity of the country has been due to free trade; but I say it is not so, I say they have robbed us of our honours in saying that. I say as guild and craft we ought to proclaim loudly to the world that to our efforts most of all the prosperity of the last fifty years has been due (hear, hear, and cheers). The population of this great city and of this country when it eats its breakfast to-morrow morning will be consuming food a very large proportion of which has been brought to this country by means of applied science (applause). It is that which has given us our prosperity. They have not taken 5s. or 10s. a quarter off wheat and other corn and eatables, but they have taken off 60s., 80s, and 100s. Wheat will be brought to-morrow from places from which it could not have been brought fifty years ago for ten times what it now costs. As a guild and craft we ought to proclaim loudly that the benefits which we have conferred are the real cause of the prosperity of the great Victorian era which we meet here to celebrate (cheers).

The Earl of ONSLOW: Mr. Raikes, my Lords, and Gentlemen—I am sure that you will be glad to hear from me the announcement that to my hands has been entrusted the last toast of the evening; but although it is the last toast, it is by no means an unimportant one. It is that of "Our Chairman this evening, the Postmaster-General" (cheers). Mr. Raikes is the head of the most important system of telegraphy in the world. It is true he is only the temporary head, and I for one at least hope that he or one of his own political complexion may long occupy that place (laughter). But, gentlemen, it is not only in my own personal and individual capacity that I am anxious to say a few words upon this Jubilee celebration of the electric telegraph, but also as representing that department of the Government with which I have the honour humbly to be connected—I mean the Colonial Office (hear, hear). Much has been said during the present year of the desirability of drawing together the bonds of the mother country and her Colonies (applause), but I venture to say that of all those bonds there is none so efficient or so strong as those of copper and gutta percha which the science of telegraphy has invented (applause); and I am anxious to take this opportunity of expressing my gratitude to Mr. Raikes for the assistance which he rendered to us during the sittings of the late Colonial Conference, in doing all that lay in his power to draw together the great commercial interests of England and of her Colonies by means of communication by post and telegraph. I feel that in Mr. Raikes we have to-night a gentleman who has not only presided over us with very great dignity and efficiency (applause), but also one who has deserved well at the hands of this country in administering that department which contributes most to the welfare of the great commercial world over which the metropolis in which we are this evening seated is, I am happy to think, the centre. Gentlemen, I give you "The Health of Mr. Raikes, the Postmaster-General" (cheers).

The toast having been cordially drunk,

The CHAIRMAN said: Lord Onslow and Gentlemen—I have to thank you very sincerely for the very kind manner in which this toast has been proposed and received, and I can only say now, as I have said previously in the evening, that I feel that your kindness is much greater than I deserve. I can only say that in departing from a subject of such magnitude and such universal interest, if one has not the knowledge of an expert at least one can bring to it something of sympathy and something of humility (hear, hear). I have sat here this evening and listened to the speeches made by some of the most eminent men of our time. I have heard recounted some of the achievements of the heroes of this great and peaceable crusade, and

Digitized by Google

I have come to the same conclusion as that recently enforced upon us by Mr. Latimer Clark that it is rather to the men of science (may I say especially to the men of applied science?) that the prosperity of this country during the last twenty years has been due than to the politicians of that epoch (laughter). I feel that it is one of the special advantages of the office which I have been called upon to hold that one comes to realise more fully than one otherwise might the great forces which are working under the surface of our complex society, and to realise how little is done by Parliamentary chatter or by political agitation compared with the great unmarked, perhaps, but resistless progress of the human mind (cheers), which is perhaps embodied in no particular aspect more thoroughly than in the progress of the telegraph system which we have met to celebrate (cheers). I have to thank you extremely for your kindness to me. Perhaps you will allow me before I sit down to read to you a telegram which has only just been placed in my hands, and which I think is a fitting climax to the festivities of this evening: "Kindly convey to Chairman of Jubilee dinner the following from the Cape of Good Hope telegraphists. Heartiest congratulations and fraternal greetings" (cheers). This, at least, is an evidence not only of the extension of telegraphy, but of the fraternal and cordial feeling which that extension entails, and I am indeed proud to be here to-night in the midst of them in assisting to celebrate this great and never-to be-forgotten Jubilee (loud cheers).

The proceedings were agreeably interspersed with a selection of music under the direction of the Electro-Harmonic Society, Miss Ethel Winn, Madame Florence Winn, Mr. Arthur Thompson, and Mr. W. G. Forington being the vocalists, each and all of whom acquitted themselves with commendable ability. No small share of the honours of the night fell to Mr. T. E. Gatehouse, who gave a masterly rendering on the violin of Mendelssohn's "Andante and Finale," which commanded universal admiration. Mr. Battison Haynes proved an accomplished accompanist.

The company separated at about half-past eleven.

In the course of the dinner the Postmaster-General sent a commemorative telegram to Her Majesty the Queen, who was pleased to return a gracious answer thereto. The full text of these messages is given below:—

(Copy of Telegrams.)

27th July, 1887.

Sir Henry Ponsonby, Osborne.

A large dinner party celebrating the Jubilee of the Electric Telegraph remember with gratitude and pride that all the progress has taken place in the happy and prosperous reign of Her Majesty, and under her fostering care.

(Signed) POSTMASTER-GENERAL.

Postmaster-General, London.

The Queen thanks you for your telegram. It gives Her Majesty much pleasure to reflect on the improvements which have been made in Wheatstone's great invention, which was first practically tested in her reign.

(Signed) PONSONBY.

TORONTO: A FAST ELECTRIC RAILWAY.—On the 5th of September the Dominion and Industrial Exhibition opens at Toronto, and several striking electrical effects are to be exhibited. The Toronto Electrical Co. are laying a railway track, over which it is proposed to run electric cars at the rate of forty miles an hour. This will be the first occasion upon which any really high rate of speed has been attained upon an electric line, although, of course, there has been no technical difficulty in the way of high speed.

CORRESPONDENCE.

PROF. FORBES' MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note that Mr. Voice, in his letter of the 17th, referring to the modified form of Webster's machine, says:—"The lines of force, as they go from one pole to the other outside of the magnet, are much more widely distributed and much less concentrated than they are near the poles; and given two conductors of the same area fewer lines would be found to act on the conductor at the middle of the magnet than on that at the pole." Now, the machine, as illustrated, appeared to me to have two conductors of presumably the same sectional area, which extended to all practical purposes outside the influences of the field. There was no question of the relative sizes of these conductors, but simply if existing theory could explain the cause of current in such a machine. If this be the question I still do not see any necessity for Mr. Voice's assumption. Had Mr. Voice shown the lines of force emitted from the side of his magnet, as well as those from the end, he would have seen the reason why a midway conductor cuts more lines of force than one at the end.

The pivot arrangement, shown further on, proves little, and till Mr. Voice can construct a pivot conforming with Euclid's definition of a line, I fail to comprehend how he is going to get his conductor outside the field without cutting some of the lines of force. Mr. Voice goes on to say, "Do not the armature cores of the Gramme, Siemens, and other continuous current machines revolve at a terrific speed through this rigidly fixed though apparently ethereal force? And does not this fact conclusively show that magnetism is separate from and independent of iron?" I am afraid I cannot see the force of this reasoning, which, if anything, goes to prove how intimately the field is connected to the coils through which the exciting current is passing.

Mr. Voice asks why a cylindrical bar magnet should not rotate axialy through magnetism as easily as the gramme ring revolves longitudinally through it. In the first place, a gramme ring, if constructed in the solid and permitted to generate currents, would not revolve easily through a magnetic field; and in the second place there is no connection whatever between the two assumptions. The magnet in the one is assumed to be revolving in and independent of its own field, whilst in the other the ring armature is revolving in the field of a fixed magnet.

A magnetic field undoubtedly gives to some extent when under the influence of a disturbing force, but this distortion may be regarded as a kind of useless friction; for if the whole of the force applied to the armature were converted into current, there would be no useless reaction in the form of an opposing force of this nature. When I made the statement referred to by Mr. Voice—that in an ordinary dynamo current is produced by the reaction of a condition that itself is instrumental in maintaining—I was puzzled to understand how this could be in the case of a permanent magnet. The field of such a magnet cannot exist without its material core, and yet Mr. Voice assumes the core to have no connection with its field when revolving round its magnetic axis, and capable of producing energy in the form of current by reaction on this field. If it really had no connection with its field, then I see no reason why this should not be; but, pray then, why is the core necessary at all?

Mr. Voice cannot see any point of analogy between a magnetic field with its core and the terrestial system. I do not see why there should be no analogy because the gases of our atmosphere can be weighed, &c. A magnetic field is, as he states, probably an ether field, and if so it is composed of finite atoms or molecules of mass as much as any other field of which the constituents are more apparent to our senses. It envelopes a solid, which has the property of attracting certain bodies, and exists as a system in itself. Our terrestial system is bound together by a force we call gravity; it is said to be an attractive force, but is more probably an impeding force due to ether impact. But whatever it be, it inter-

Digitized by Google

links the whole, and causes both the material gases and earth to revolve together as a system. A magnetic field is also maintained by a constraining force, and as the field cannot exist without a solid core, analogy would lead us to expect that the core and field are as intimately interlinked by virtue of the magnetic force as the gases and earth of our terrestrial system.

Mr. Snowdon has placed the subject at issue in a clear light, but I do not agree with him respecting a molecular chain, nor do I see how on this theory the molecular constituting the disk armature of Prof. Forbes' machine would receive their necessary oscillations.

If, however, we divide the armature of this machine into a number of concentric rings, it will be seen that the outer rings, containing more mass than the inner, will have a lower E.M.F. induced in them than the latter, although the same number of lines of force be cut in each case.

Perhaps this action becomes clearer by aid of analogy. Let any of the inner rings receive the same quantity of heat as any one of the outer, the inner ring, having less substance, would then be of a higher temperature than the latter, and a transfer of heat action would take place between the two, till each had arrived at the same temperature. Hence it will be seen that the same amount of energy was imparted to each, with resulting differences in intensity or potential.—Yours, &c.,

N. G. THOMPSON.

4, Queen Victoria-street, E.C., July 26, 1887.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may help to elucidate the theory expressed in my letter in your last issue if I show how it may be applied to account for the currents exhibited in the experiments with a cylindrical magnet, as described by Mr. Voice in the same issue.

Mr. Voice accounts for the effects described by supposing the magnetism not to revolve, but it is quite unnecessary to take that view, contrary to what he supposes.

It is impossible for him to make the necessary contacts with his magnet without placing a conductor in its field which will in a measure "scotch" the lines of force as they go round with the magnet, and accordingly retard them so as to make them cut through the magnet itself in honest proportion. Of course, if other conducting masses be also present within the sphere of the bar's magnetism, their retarding effect on the rotation of the lines will also have to be considered.

Were the currents observed by Mr. Voice really in the proportion 1:2, or did he only predict that?—Yours, &c.,

Staveley Ironworks, July 22nd, 1887. R. SNOWDON.

[We have also received a letter from Mr. Scattergood, but it did not reach us in time to have the blocks cut for this week's issue.—ED. *E.*]

THE USE OF PARAFFIN WAX AS AN INSULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst making a sparking coil we had an experience particulars of which may interest some of your readers, who may have had a similar failure, without being able to divine the cause.

The coil had been treated in the ordinary way with paraffin wax of low melting point; to increase its bulk for a mechanical reason it was cast in a mould with a harder wax. Previously the coil had given a very good result, but after this treatment it was with difficulty that any spark could be obtained. We are under the impression that the cooling and contraction of the wax in the interior of the coil after the setting of the harder exterior wax must have left the mass of the wax in the coil full of fissures, which undoubtedly must have been vacua, as no air could penetrate the already hard external coating. To test the accuracy of the aforesaid hypothesis, and, if possible, remedy the defect, we remelted and removed the whole of the harder wax. The spark after this was as good as at first.

We would remark that the same cause might detract from the efficacy of a coil with wax of *one* density if the exterior were allowed to harden first by rapid cooling.

As this difficulty might occur in other apparatus we would point out the necessity of cooling *very slowly* where wax is used for insulating purposes.—Yours, &c.,

L. S. M. PYKE, F.C.S.

Devonshire-place House, N.W. HARRY T. BARNETT.

MEASURING MAGNETIC INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Kapp's excellent paper "On the Pre-determination of Characteristics of Dynamos," we are told that "an experiment made once for all is sufficient to determine this constant for all sizes of a given type

Is the manner in which Mr. Kapp carries out this experiment the same as that employed by Dr. Hopkinson, viz., by putting a wire loop round a magnet limb, and afterwards round the armature, and by measuring the magnitude of induction by a ballistic galvanometer? or has he found another more workshop like method?

I should feel very much obliged to Mr. Kapp by his favouring me with an explanation.—Yours, &c.,

FREDERICK DREXLER, Electrical Engineer.

Vienna, V24, Straussengasse, July 22nd, 1887.

HOW WE SAW THE REVIEW AT SPITHEAD.

Long before this article reaches the eyes of our readers the splendour of the spectacle at Spithead on July 23rd will have been described in glowing language in the pages of the daily press. These facile writers, however, are unable, with all the witchery of word-painting at their command, to adequately describe the scene presented by the Naval Review then held to celebrate the Jubilee of Victoria. Nor must it be expected that pens ordinarily devoted to the dry facts of science can hope to pourtray with greater vividness the scenic effects of a day long to be remembered in history, and never to repeat itself to those who had the good fortune to be witnesses thereof.

The electrical profession is to be congratulated upon the part their handiwork has taken in the display. He would have been a bold prophet who in 1837 had suggested one tithe the conquests made by electricity during the half century that has elapsed, but to-day it plays by no means an insignificant *rôle* in the world's affairs. The representatives of the Telegraph fleet present at Spithead formed a startling and a splendid proof of the electrical progress of fifty years. The Telegraph ships, so far as we saw them, were the "Monarch," the "Silvertown," the "Seine," the "Mirror," the "Electra," and the "John Pender." The three last vessels belong to the Eastern Telegraph Company, the "Seine" to the Telegraph Construction and Maintenance Company, the "Monarch" to the Government, and the "Silvertown" to the India Rubber, Gutta Percha and Telegraph Works Company, better known as the Silvertown Company. Our coign of vantage was on the "Silvertown," and it may interest our readers if, after this brief introduction, we attempt to describe the proceedings of the day. By the kind and courteous attention of the Silvertown Company we were provided with a berth on board the ship. On Friday afternoon, repairing to Waterloo Station, it was soon evident that something of more than ordinary interest occupied the attention of the railway officials. Cabs blocked the approaches to the railway, and the enterprising travellers had to make their way on foot, to find the station crowded with passengers bound to Southampton or Portsmouth. Train after train filled and was despatched, and ultimately with little demand on our patience we found ourselves at Southampton. Friendly faces appeared and friendly hands were grasped, giving a hearty welcome to the incomers. The guests of the Silvertown Company will long remember the considerate manner in which creature comforts were provided, and bear testimony that no pains had been spared to render the trip as enjoyable and pleasant as possible. When those who were to sleep on board arrived at the "Silvertown," which was lying off Netley, they found familiar faces of others who had come round with the vessel from the Thames. "Music arose with its voluptuous swell," and song

Digitized by Google

succeeding song, carried us well into the small hours of the morning. To the landsmen, the ship method of marking the passage of time by the striking of the bells recalls at this moment the words of Poe :—

What a world of merriment their melody foretells!
How they tinkle, tinkle, tinkle
In the icy air of night;
While the stars that oversprinkle
All the heavens seem to twinkle
With a crystalline delight,
Keeping time, time, time,
In a sort of Runic rhyme,
To the tintinnabulation that so musically swells
From the bells.

A brief respite in the round of gaiety, a short journey to the land of nod, a cheery awakening to "Coffee, gentlemen!" brings us to the morning of the eventful day.

Queen's weather is proverbial, and this year has proved no exception to the rule. Saturday morning then gave forecast of a glorious day. Netley Hospital loomed across the water clear and distinct. A further contingent of visitors arrived, and the "Silvertown's" anchor was raised. Quietly steaming towards the crowded waters at Spithead, the vessel ere long reached the lines of warships. The steamer moved slowly through the fleet and back again before dropping anchor near to the "John Pender." Who can describe the sight as it should be described? Ship after ship, gay with bunting, and as spick and span as only men-of-war can be, crowded with brilliant uniforms, burst successively upon the view. It is not our province to discuss the various types of ships—there they all were, from the swift torpedo boat and torpedo catcher, to the ugliest, heavily armoured, tower-topped and turretted modern engine of naval production. After going through the lines there was time to look around, and whichever way the eye turned it fell upon proofs of England's maritime greatness. Perhaps the most effective and certainly the finest sight of the day was the procession of troop ships. These vessels are acknowledged to be some of the finest specimens of naval architecture ever produced, and while æsthetic tastes have certainly not been consulted in designing our modern war ships, surely the most fastidious taste would find little fault with these beautiful vessels.

The Queen has started, and the sound of the signal gun bursts upon the ear. Immediately along the line the answering sounds arise as the salute of twenty-one guns announce the arrival of Her Majesty. The swirling smoke for a moment hides the vessels from our view, but the gentle breeze soon carries it off, and almost ere the last "boom" has sounded the air is once more clear, and from a hundred lips the words go forth "There she is!" as the Royal Standard is seen coming up the line of battle ships. The progress of the Queen's yacht is watched with interest, but we are too far off to hear the "hurrahs" of the sailors who man the yards of the vessels. On the return journey the yacht casts anchor in the middle of the line, and signals flutter in the breeze. Soon we perceive that these signals are to command officers to the Royal yacht, as boats put off from the various vessels within sight, all going towards the Queen's yacht. From the reports in the daily papers we understand that the Queen expressed her warmest approval of the pageant provided to do her honour. Some two hours were spent in this ceremony, and then the "Victoria and Albert" proceeded onwards. The departure of the Queen was signalised by a salute of twenty-one guns, as was her arrival, but the spectacular effect of this later salute was far more brilliant than that of the earlier one. A bank of dark cloud had arisen on the horizon, showing up as a background with great vividness the flashes of the guns. The spectator would see a flash of flame rushing out of the side of the vessel, and through the remnant smoke of the preceding discharge, followed by a whirling puff of smoke, and after that came the dull boom. Then all was silent. The smoke gathered in a cloud and was soon carried away shoreward. Again came a period of waiting for the grand firework display that was to bring the memorable day to a conclusion. But time did not hang heavy with those on board the "Silvertown," while some of the other vessels that had not previously gone through the lines took the opportunity of doing so.

Eight o'clock. A moment ago flags were fluttering in the breeze from every masthead, but simultaneously throughout the fleet the flags came down with a run. It was a pretty sight. Night came on apace, and now came also the time for the electricity to show what part it was to play in the spectacle. During the day curious eyes through powerful glasses had attempted to make out what preparations had been made on board the ships for the illuminations. Little, however, was to be learnt save that lines of incandescent lamps could be detected. As darkness spread over the water brilliant lines of light from incandescent lamps flashed out, now here now there, till the permanent lighting of the evening, if we may so term it, was general. From various mastheads, too, flashed out powerful arc lamps, giving a brilliant effect. Each vessel, also, had arranged incandescent lamps to shape the monogram "V R," the letters being in some cases over 14ft. in height.

A signal comes in the wild weird scream of the siren. Every one is on the *qui vive* to know what it means, when bursting upon the eye comes one of the most brilliant displays that it has been the lot of sight-seers to witness. From deck to masthead the men-of-war are illumined with red and blue and yellow lights, while clusters of rockets rush upwards through the clear air, bursting in a thousand brilliantly-coloured scintillations. Vieing with the men-of-war our own vessel enters into the pyrotechnic competition. From end to end of the bulwarks, from all our yards, sailors are placed, each with coloured fires. At a given signal the vessel is illumined, and cheer upon cheer from the surrounding ships show how successfully. Meanwhile flights of rockets are being sent up, and the largest and most brilliant of all the search lights upon the water sends forth a powerful beam, lighting up everything upon which it is cast. The sight-seers upon Ryde Pier feel its power and turn away from its direct beams. But soon these beams are curtailed, for the smoke is hanging thick over the fleet, fog has arisen, and the atmosphere is no longer clear. We hear the rockets hurtling up through the smoke, see the reflection of the light when they burst, but except when they pierce through the smoke cloud and burst in the clear space above the effect is somewhat marred. The scream of the siren has been heard again and again, bringing about concerted action far and near, each successive effort, perhaps, being more beautiful than the last; but to our eyes the most effective display was by the sailors playing at battledoor and shuttlecock with coloured balls of fire. This effect, so far as one could make out, was from a general distribution of Roman candles all over the decks and lower rigging, the coloured balls of flame thrown out by these candles describing all kinds of curves, intermingling in beauteous confusion, giving a *coup d'œil* which could hardly be surpassed.

But the crowning effect was to come. The signal was once more the wail of the siren, and instantaneously the brilliant beams from the search lights from every ship flashed forth. It is impossible to describe the scene. The direction of the beams had been privately arranged, and it will be understood that the effect was grand. At one time they would converge to a distant point on the water, at another time the brilliant beams of light were directed to a point skyward, forming a "crown of glory."

Here we conclude our report. In our estimation the most instructive lesson of the day was to be learned from the fleet of cable ships. We do not care to moralise, but the thoughtful mind could not but contrast these vessels, and their work, with those we went out to see.

THE EXPERIMENTAL LINE OF THE ELECTRIC TRACTION SYNDICATE AT SOUTHWICK.

On Tuesday last, upon the invitation of the Electric Traction Syndicate, the representatives of the technical journals were present at "a private demonstration of electric traction" on the line between Shoreham and West Brighton. The line itself was built by a local company some years ago, but has never paid its way, and it has been in the hands of the Syndicate for experimental purposes during the past twelve months, during

Digitized by Google

which period an elaborate series of tests have been carried out. The total length of the line is about 4½ miles, and presents features which are of considerable value for the purpose in view. The gradients are numerous and in some cases exceptionally severe, rising to 1 in 20 where the road crosses a bridge at Southwick, and there are two sharp curves of about 28 yards radius, one of which is on an incline of 1 in 100. When to this it is added that the road has not been maintained in very first rate order, it will be seen that the line is particularly well adapted to test the capabilities of any system of traction. Indeed, it may be remarked that Messrs. Aveling and Porter, the engine builders, have been experimenting with a new type of steam engine upon the same line concurrently with the electric trials. The average coefficient of traction has been found to vary between 42 and 55lb. per ton, according to the state of the metals; upon a well-laid London line this coefficient does not usually exceed 30 to 35lb. per ton.

The engineers of the Syndicate are of opinion that while electric traction upon lines where the cars follow one another at short intervals is best applied upon the cars themselves, yet that a wide field exists for the use of electric locomotives upon suburban lines where heavier loads are carried at longer intervals, and the conditions approximate more nearly to those of a railway. The trials upon Tuesday last began, therefore, with a short run upon an electric locomotive car weighing about 12 tons, and designed to draw a bogie car, with seats for 60 persons, at a mean speed of 8 miles an hour, additional accommodation for 14 persons being provided upon the locomotive itself. The motive power is obtained from a set of 168 A size Tatham cells, discharging at 50 to 60 amperes, with a capacity of 200 ampere hours. The motor, which is of the Immisch type (SM9 on their list), series wound, runs at 650 revolutions. The armature is 9in. in diameter, and is geared direct to the driving wheels by pinions at each end of the spindle, which mesh with internal teeth upon a circular rack on the wheel. The ratio of the teeth is 10 to 67. The motor is suspended by sleeves on journals cut in the axles, which are of steel, and has a tension bar from the centre of the fields to the end framing, to act as a fulcrum. But although this gearing has given good results in practice, yet it has been considered desirable to seek for a less expensive form of gear of equal efficiency; this having, it is believed, been found, it is not intended, as a rule, to resort to the arrangement just described. For this reason the trip of the locomotive was not of great length, nor were any measurements taken.

Returning to the engine house at Southwick a self-contained car was next tried, upon which the party made the journey to Shoreham. At this place a halt was made for lunch, and afterwards the car traversed the whole length of the line to West Brighton, attaining a mean speed of slightly over 11 miles an hour; the maximum speed probably approached 16 or 18 miles an hour on some of the inclines. This car is capable of seating 20 passengers, and by itself weighs one ton; the weight of motor and gearing is one ton, and the accumulators 1·75 tons; a total rolling load, when full of passengers, of about 5·25 tons. The wheel base measures 5ft., and the wheels are 2ft. 6in. in diameter. The cells, which are eighty-four in number, are of the Tatham type, B size, with a normal discharging rate of 45 to 50 amperes, and a capacity of 150 ampere hours. They are divided into two separate batteries, each battery being again divided into two halves. By means of a suitable switch, designed by Messrs. Immisch and Co., the two halves of each battery can be connected either in parallel or in series, and the two batteries can also be connected in parallel or in series with each other. Out of these four possible arrangements it will be seen that two amount to the same thing electrically, so that only three different speeds are obtainable by this means. In actual practice it has been found that these three speeds fulfil all requirements.

The motor is again of the Immisch type (SM7), series wound, and runs at 1,000 revolutions with 160 volts and 40 amperes. The experiments carried out by the Syndicate have largely been directed to the question of heavy motors running at slow speeds geared direct, *versus* lighter motors running at higher speeds with second-motion gear. With slow speed motors the question of weight assumes great importance, not only because the motor itself must necessarily be comparatively heavy, but because at slow speeds the torque is so great that the gearing and all structural parts connected with this or the motor have to be additionally strengthened. These additions to the dead weight, combined with the slower speed, necessitate also a greater current in starting and upon inclines, and thus reacts injuriously upon the batteries. A speed as low as 350 revolutions has been tried, but the experience gained has led to the conclusion that a considerably higher speed is desirable, even although the gearing becomes more complex. The motor now preferred runs at 1,000 revolutions, and drives by means of chain gearing.

The chains are of a type specially designed by Mr. Hans Renolds, of Manchester, and the links are exceptionally heavy. By means of an intermediate shaft the speed of the driving wheels is reduced in the proportion of 1 to 9, and means are provided for taking up the slack of both chains by shifting the journals. The gearing runs with great smoothness and an almost entire absence of noise; in fact, the car runs without more noise than a horse car.

The motor weighs about 5½ cwts., and has an efficiency of conversion at full load of 85 per cent. Its average working efficiency probably lies between 75 and 80 per cent. By winding the armature with smaller wire this could probably have been increased without reducing the normal output; but the element of safety which exists in an armature capable of taking an excessive current would be reduced in proportion. In this case the factor of safety as regards the sectional area of the wire is so great as to admit of the car being stopped and started upon an incline of 1 in 20. It was proposed on Tuesday to repeat this experiment, but time did not permit. The current, however, probably exceeded 100 amperes under this test.

The readings of the ammeter taken during the run showed that under an E.M.F. of 80 volts the current averaged 35 amperes on the level at a speed of 8 to 10 miles an hour, rising to 45 amperes on an incline of 1 in 120. When the cells were placed in series, giving a terminal E.M.F. of 170 volts, the mean speed increased to 12 or 14 miles on the level with a current of 45 amperes. On the incline of 1 in 20, and going round the sharp curves, the current increased to 80 amperes. These figures are little more than approximate, but were taken as a rough verification of the results obtained by more careful tests made at leisure by the engineers of the Syndicate. The limits of our space do not permit us to give a specimen of these tables in our present issue, but we shall probably return to the subject at an early date.

The Electric Traction Syndicate is certainly to be commended for the careful and thorough manner in which they have proceeded to work out the numerous problems connected with the details of the subject; and especially for their determination not to come before the public until a long series of trials of a thoroughly practical character had enabled them to undertake business with perfect confidence in their ability to carry it to a successful issue.

COMPANIES' MEETINGS.

Submarine Telegraph Company.

A meeting of the proprietors of this Company was held at the offices, 2, Throgmorton-avenue, London Wall, on Monday last, under the presidency of Sir Julian Goldsmid, Bart., M.P.

The SECRETARY (Mr. S. M. Clare) having read the notice convening the meeting, the Company's seal was affixed to the register of shareholders.

The CHAIRMAN: Gentlemen, I have to make a few observations on the report, which I expect you will allow me to take as read, as you have on previous occasions. You will observe that there has been a fair increase of traffic, but I, for my part, do not consider that that increase is altogether normal. I have several reasons for that opinion. The first is, that it is a surprising fact that there was an enormous increase of messages owing to the earthquake in the Riviera last winter—that was early in the year. The second is, that shortly afterwards there was an alarm of impending war between France and Germany, which caused an immense amount of telegraphy between continental countries and England; and the third was, that it happened that, in consequence of the vast number of august visitors who came to this country in honour of the Jubilee, there was a large temporary increase in the number of messages. I regret to say, therefore, that in my opinion this increase, which is satisfactory so far as it goes, does not appear to be a permanent one owing to there being temporary causes to account for it. But there is one other satisfactory fact

Digitized by Google

to relate, and that is that practically, for the present at least, we seem to have come to the end of the fall in the number of words which are comprised in each message. That is a matter so important that it is specially stated in the report, and you will there see how it stands. On the whole, I do not consider that the position is unsatisfactory, because if we have come to an end of the fall in the number of words per message, there must be before long a steady increase in the business of this Company as there is in the business of the world generally. I think that you will probably expect me to say something about the future of this Company; but on the whole I believe the less I say the better it will be, because, first of all, we have still rather more than a year and a half to exist under present conditions, and what the future conditions may be I am not in a position to say. You will have observed that questions have been asked of the Postmaster-General in the House of Commons with regard to his wishes with respect to the end of our contract, and I believe similar questions have been addressed to the French Minister in the Chamber of Deputies, and both ministers have observed a due reserve on the subject, merely saying that it would occupy their attention. It appears to me that although I do not occupy so important a position as a minister, still, as your minister, if I may so speak, I consider it is my duty to say that we shall do all that we can to maintain the interests of this Company, and that we must ask you to show us that confidence which you have hitherto placed in us. There is another point upon which I might say a word, namely, that our former Director, Mr. Robert Bourke, who is now Lord Connemara, left the Board when he was appointed to the high office of Governor of the Presidency of Madras. I was in hopes that we might have secured the services of a most illustrious man—there is no need to mention the name—to fill his place, but we did not succeed, although I am glad to think that we have obtained the services of an able and intelligent gentleman, whose name will be submitted to you for approval—Mr. Gathorne Hardy, the son of Lord Cranbrook. He is a most experienced gentleman, and capable of giving us valuable assistance, and in securing him we have, I think, secured a valuable addition to the Board. That is the sum and substance of what I have to say to you. I do not think there is anything special in the present condition of affairs. I believe that we shall have quite a normal half year, and that at the end of it I shall have to report to you certainly not a large increase, if, indeed, I have to report any increase at all. But, on the whole, considering that our property is in good order, and that we have done our best to satisfy the public, in whose interests we work as much as in those of the shareholders, I think we may congratulate ourselves on our present position, and I have much pleasure in moving the adoption of the report.

The Hon. ASHLEY PONSONBY seconded the motion.

A SHAREHOLDER wished to be informed what was the basis upon which the proportion of the receipts as between the two companies was calculated.

The CHAIRMAN said they were aware that the French was the original company, but the English one was established subsequently for the purpose of adding to the number of cables, and it was by arrangement between the two companies that it was deemed easier to obtain capital in England under the circumstances than it was in France. They must remember that in the early days of its existence the Submarine Company worked, like many other pioneers of useful work, without any remuneration at all, and people who talked about their receiving large dividends now should bear that fact in mind. What they now received went to counterbalance their early bad fortune and give them just a fair average dividend. The proportion of receipts as between the two companies were represented by the figures—English 83·6, and French 16·4.

The motion was then put, and carried unanimously.

The CHAIRMAN next moved "That, in accordance with the recommendation of the court, a dividend for the half-year at the rate of 12 per cent. per annum, payable on and after the 1st September next, be now declared." He might mention that the meeting was held a week earlier than usual as a matter of personal convenience to himself, and, he hoped, at no inconvenience to the proprietors.

The Hon. H. R. BRAND seconded the motion, which was agreed to unanimously.

The retiring Directors, Sir Julian Goldsmid and the Hon. E. Chandos Leigh, Q.C., were subsequently re-elected to their seats at the Board, and the appointment as a Director of the Hon. J. S. Gathorne Hardy, M.P., was confirmed.

The auditors, Messrs. William R. Cole and Thomas Dakin, were then re-appointed, and the proceedings terminated.

Anglo-American Telegraph Company (Limited).

The half-yearly general meeting of the proprietors of this Company was held at Winchester House, 50, Old Broad-street, on Wednesday, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last half-yearly meeting, which were signed as correct by the Chairman.

The CHAIRMAN: I presume, gentlemen, that you will take the report as read. That being so, it now becomes my duty to move its adoption, and in doing so to make a few observations on the working of our institution for the last half year and our prospects. The first observation I am led to make is that during the past half year we have carried a very large volume of traffic, and have done it most efficiently. In fact I am tempted to tell you a little anecdote which I heard the other day, to show the efficiency of the working. I was told that a gentleman who wished to get an answer from New York in the shortest space of time had an answer in either four or five minutes, and he was so incredulous that he went back and had the message repeated. He could not believe that the answer had come in, and he was quite willing to pay, in order to satisfy his curiosity a second time. The volume of traffic, as I said, has been very large; but I am sorry to say that when turned into £. s. d., it is not quite so satisfactory. We have, however, whatever satisfaction may be derived from the fact that the figures which are open to us lead us to the conclusion that the pecuniary position of our rival is not a happy one either; and therefore it seems that the hardships from which we are suffering are rather in the nature of things than resulting from anything defective in the management of your Company. I will not attempt to give you any figures showing the increase of the traffic as compared with former periods, and for several reasons, which I will tell you. In the first instance, if we compare with the corresponding period of last year we should not be comparing with a period during which we were carrying our traffic at the same rate, and therefore the comparison would be entirely fallacious and misleading. In the next place, if we compare with the previous half year, during which we were carrying at 6d. a word, our experience is that the second half of the year is always a great deal more productive than the first half, and that in itself would vitiate the comparison also. There is another element in the matter not to be neglected, that is, the withdrawal of the French company from the "pool," the right to which withdrawal we, of course, dispute; but that is only in a parenthesis. That fact, however, would also introduce an element into the accounts which would render any comparison fallacious I therefore will not trouble you with any comparison of the dates, but content myself by saying that the 6d. tariff has brought a satisfactory and substantial increase both in the first half year in which it was in operation and in the second half year, which is the bad half year as compared with the first half, which is the good half. Gentlemen, so much with respect to the traffic; now with respect to our plant. I may tell you that our whole system is in excellent condition, with the single exception of which you are all aware, as it is alluded to in the report—the breakdown of the Brest-St. Pierre cable. That is the oldest Atlantic cable in existence, and it was still working up to the time of the break. The break took place in November, and perhaps some observations may be made as to why we did not send at once to repair it. But gentlemen who are conversant with cable work in the Atlantic know that it would be absurd at that period of the year to send out an expedition to repair a cable. The ship, I believe, is now on the ground, and in the act of repairing the cable. The period which intervened has not, however, been lost, because we have used our ship in taking soundings in the neighbourhood of the break, which I expect will be very useful to us in making the repair. If you look at the accounts you will see that we have earned £6,000 by the hire of our ship in the meantime. As I told you, the plant is in good order. As to the accounts, I do not think there is any peculiar feature in them. The expenses are a little higher than in the corresponding half of last year; but we have been carrying an enormous additional traffic, which cannot be carried without additional cost. So much as to the past. With respect to the future, I have very little to tell you. You have all probably seen reports from the New York newspapers with respect to discussions for an arrangement of the difficulties between the companies, and all I can say is this, that you are aware of the proverbial connection between fire and smoke, and from that I am led to believe that such communications may have taken place; but as far as your Company is concerned, or our sister Companies, we have had no proposal laid before us with which we could deal, and therefore, as far as I am concerned, and as far as you are concerned, we are precisely in the same position with respect to competition for the traffic that we were in when I last addressed you. When I announced to you this time last year the adoption by your Directors of the policy of trying at a low rate to stimulate the traffic—which policy, by the way, was, as far as I could see, accepted very favourably in this room—I told you that it was a policy that I believed in the long run would be successful, but that it was one which in the meantime would make considerable drafts on your patience and forbearance. Now, that is the case. The traffic has been stimulated, and has very largely increased, and is increasing, but it has not yet reached a point at which we can pay you anything like a satisfactory dividend. On the other hand, we are very much in the hands of others with respect to any change of policy. I do not advocate a change, but if we wish for it we are in the hands of other people in a large degree. We cannot make a change without the consent of other parties, and those parties as yet have given no indication either of their intention or desire to make any change. Gentlemen, this is a matter upon which I do not want to dogmatise or to lay down any hard or fast lines, or to use any expression which would interfere with any arrangement that might be considered advisable for the companies to adopt. I told you this time last year that we adopted the 6d. rate not as preferring 6d. to any other figure, but because it was a very low rate, and one which we expected would have the effect of stimulating the traffic. I still hold that opinion. I have the most confident conviction that if by any arrangement we were to raise the rate at present by a large figure we should infallibly have additional competition. That has been what has resulted from this arrangement in former times, and I believe the experience derived has led your Board to the conclusion that such a proposition would be highly inexpedient. My own conviction is that we ought to go on—I do not say at 6d., or at 1s.—but that we should fix the rate at a very low figure, and go on in the hope of stimulating and increasing the traffic, and thereby making a livelihood for ourselves. I think it is essentially—eminently—a case in which you ought to trust your Directors. If you do not think we are managing your business satisfactorily, and to the best of our ability, and as well as it would be managed by others, I should advise you to get rid of us, and to get those who you think could do better for you; but as long as we are your Directors, and you continue us in that position, I must ask you per-

Digitized by Google

sonally, and on behalf of my colleagues, not to give us a half confidence. We are doing all we can. We are endeavouring to economise in every way, and we hope the continuance of our policy will enable us to pay you, if not a large dividend, at all events a satisfactory one. With these observations I leave the matter in your hands, and I beg to move "That the report of the Directors and the accompanying statement of accounts to the 30th June, 1887, submitted to this meeting, be, and the same are hereby, received and adopted."

The Marquis of TWEEDDALE formally seconded the motion.

Mr. THOMAS SMITH (York) said he would support the adoption of part of the report, but he could not approve of the whole of it. He agreed with the Chairman's remarks as to the 6d. tariff; and the improvement in the traffics compared with the corresponding period of last year was very encouraging, and showed, to his mind, that the 6d. rate was an increasing success. For four months of the corresponding period of 1886 the 1s 8d. tariff was in force, as against 6d. in the whole of the past half year. The December half year they always considered, as the Chairman had said, the better half year, and in that half year they brought forward a balance of £2,423, leaving the net takings for the six months £87,384, compared with £100,534 in the six months now under review—to the 30th ult. In making that comparison, it must be remembered that they brought forward not a farthing in the half year just closed. After what the Chairman had said, he thought they might look forward with confidence to the coming half year, the best half of the year. He believed that they would consider with him that the sixpenny rate was progressing very satisfactorily, and that they had nothing to do but to sit still and work at it. In his opinion the future policy of the Company must be based on the 6d. tariff. Let them give it two or three years' trial. They would suffer from the want of dividend during that period; but he was quite willing, though a large shareholder, to forego his dividend for the present—that was, if the Directors would be fair towards them and divide what the Company earned. He did not agree with the Directors' policy as regarded the third paragraph of the report. At the last meeting the Chairman asked the shareholders for their patience, forbearance, and support, and he (the speaker) thought they had granted that request right loyally. Taking that into consideration, and the fact that nothing had been brought into last half year's account, he thought the Directors should have made the dividend on the ordinary stock 10s. per cent. and on the preferred stock £1 per cent. After the shareholders had suffered as they had, the Directors ought to meet them in the most liberal way, instead of proposing to carry forward a balance to the next half year of 50 per cent. of the net earnings of the last six months. Such a proposal he regarded as preposterous. And what were they carrying it forward for, seeing that they had £84,500 uninvested? He did not think it could be said that there was any shortness of money, with £84,000 doing nothing, and for which they had received £165 as interest. At the meeting last February, too, they were promised a detailed list of the investments.

The CHAIRMAN: Have you not got it in the report?

Mr. SMITH said he did not consider it a detailed statement, such as that given by Mr. Pender in the case of the Globe Telegraph Company. There was an item of £13,000 given as "other securities." Was that a detailed statement? Such a statement would only have to be done once, and it would really cause practically no trouble. He was glad to hear the Chairman speak about economy, but he could find no evidence of it in the accounts. In conclusion he moved as an amendment, "That the report be adopted, with the exception of the part of paragraph 3 which states that £18,323. 6s. 8d. be carried forward, and in lieu thereof that a dividend of 10s. per cent. be paid on the ordinary stock and 20s. per cent. on the preferred stock."

Mr. C. E. DAVISON seconded the amendment. The Directors must be aware that for a long time the shareholders had suffered from the want of dividends, and it was only right that, instead of £17,500 being now distributed, £35,000 should be divided among them, which would be the effect of carrying Mr. Smith's amendment, and which he urged the Directors to support.

The CHAIRMAN: I am not now going to answer Mr. Smith's observations, but I wish to say a few words about his amendment, as to which it would be perfectly useless and a waste of your time to have any discussion. I am precluded from putting it to the meeting by the Articles of Association. The shareholders cannot declare any larger dividend than that recommended by the Directors, and I should be forfeiting all claims to your confidence, and should be violating my duty if I put this amendment. I have the greatest possible sympathy with the shareholders. The fact is that this is an interim dividend. We retain this fund in our hands, but it is only an estimated surplus. It should be remembered that we are engaged in litigation with the French Company, and that we have at this moment a very expensive repairing expedition going out. We may require money for that, and at all events we have to the best of our judgment done what we thought was for the true interests of the shareholders in declaring this interim dividend, with the prospect that during the year we shall be able to give them something more.

Mr. WILLIAM ABBOTT said he had been very pleased to find Mr. Smith—a gentleman whose remarks at the meetings were deserving of every respect—so strong an advocate of supporting the Board in the policy they had adopted respecting the 6d. tariff. He himself at the last meeting had not agreed with that policy, because he had thought it desirable that some arrangement should be made by which the tariff should be raised to 1s. He had, however, completely altered his opinion, for the 6d. tariff did not suit their competitors at all. He thought they should continue the tariff, and wait and see the result. At that meeting he was particularly desirous that they should give a unanimous support to the Directors. He did not think the detailed information respecting the cost of the securities of the renewal fund was necessary, and what he himself admired about the report was its simplicity. They had securities valued at £882,000, with £84,000 uninvested. He thought it would be very satisfactory if they could be told whether the present market price of the £882,000 was in excess of the actual cost price of the securities. He begged the Directors to invest nothing further in the Canadian Pacific Railway Company.

The CHAIRMAN: It is a first mortgage.

Mr. ABBOTT said he had no faith in the Canadian Pacific Company. He was glad to see the legal expenses so small, and astonished to see Mr. Burt looking so well notwithstanding. He regretted that Mr. Smith had spoiled his statement by the amendment which he had proposed, and he thought that they should on that occasion show their competitors that they were "full of fight." He would be sorry to see distributed the £18,000 which the Directors in the report had suggested should be carried forward.

Mr. GRIFFITH said he considered that the argument adduced by Mr. Smith in support of his amendment was unanswerable. He maintained that the £84,000 referred to ought to have been invested to produce 3 per cent. at least. He entirely agreed with Mr. Smith. As to the amendment, the Chairman took a very restricted view of what the Articles of Association provided. They could put the amendment in this way—that they would not receive the report, that they would send it back, and that unless the Directors would declare the extra dividend which Mr. Smith proposed, they would not pass the report. Remembering the additional expense involved by the increased work that had to be done with a sixpenny tariff, he reckoned that they would have to earn four times the amount they had earned with the 1s. 8d. tariff before they could even attain the wretched position they were in with the higher tariff. He supported the amendment. The time had come when the Articles of Association should be altered.

Mr. JOHN NEWTON contended that the revenue earned by the reserve fund ought to be added to the general revenue of the Company, and not put to the fund.

Mr. HERBERT SMITH (Gray's Inn) maintained that it was unnecessary to carry forward the sum of £18 000 as proposed in the report.

Mr. HUMPHREYS wished to know why it was that the £84,000 had not been invested. He viewed the report in an unfavourable light, and he believed that the reduction in the tariff from 1s. 8d. to 6d. was an act of temper, the whole circumstances of the case not having been taken into consideration.

The CHAIRMAN: I regret very much that we have not the admiration for our report of the gentleman who has just sat down, but I think he takes rather a prejudiced view of the conduct of the Board, because he says that the adoption of a 6d. tariff was an act of temper. I can only say that so far from being an act of temper, when one commits an act under the influence of temper one acts hastily, but I never, since I have been on the Board—now for a good many years—remember any act that was taken with greater deliberation, more circumspection, and more consideration of all the circumstances of the case. The gentleman has also said that the rate would never rise beyond 6d. That view is certainly not derived from any observation I have made, for I guarded myself most carefully in saying that it was a low rate we went in for with a certain object, and that we can never bind ourselves to any particular rate as one we would arrive at. So much for Mr. Humphries. I now proceed to answer as well as I can the different observations made. Mr. Smith took occasion to animadvert on the amount of the dividend, and said it might have been 10s. per cent. He is quite right. It might have been 10s. per cent; but had we declared a 10s. dividend we should have divided up very closely on a balance which was only an estimated balance. I wish the stockholders to remember that this is not the final dividend. This is merely an interim dividend. You will, I hope, receive another and I trust a larger dividend next quarter.

A SHAREHOLDER: You told us that six months ago.

The CHAIRMAN: I do not pretend to infallibility, and if I did venture to prophesy I think it probable that I might have been incorrect. But still I had not the same ground then as I have now, because we have now, so far as an estimate goes, the money in hand, and we shall pay up as closely as possible in the next half year. Mr. Smith and some other gentlemen made some observations about the uninvested balance of the reserve fund. That balance is a sum which is probably not yet paid. Another portion of it is a sum which we shall have to pay in the course of a few days for the expense of the repairs; and now I put it to any of those gentlemen—I ask Mr. Abbott, as a practical man, does he think it would be wise for us as directors to invest money, incurring the expense of stamps and brokerage, which we should have to pay in two or three months?

Mr. ABBOTT: You must pay the broker.

The CHAIRMAN: We have sent out 300 miles of cable, which has to be paid for. It is really to save the money of the Company that we do not invest this sum. Then there is a small amount of £13 000 of which Mr. Smith made a great deal in point of argument. I wonder if Mr. Smith has ever read such a thing as the account of a charitable subscription, where a number of small sums are put down under one total. This £13,000 is put down here on the same principle. They are small investments not worth fully mentioning; but if Mr. Smith has the least curiosity he really only has to go to the offices of the Company and Mr. Wells will tell him.

Mr. SMITH said that he wanted the information not merely for himself, but for the benefit of all the shareholders. They could not all go to the offices for the information.

The CHAIRMAN: I think if you get the information respecting £382,000 it is taking rather a microscopic view of things to want the details about £13,000. Mr. Abbott asked what is the total value of the investments to-day. As nearly as we can calculate, taking the middle value, the securities are worth about £25,000 more than they cost us. As to the Canadian Pacific Railway, it was very good advice—[Mr. ABBOTT: It was only a hint]—given by a stockbroker to an investor who had come to consult him; but I do not think the Canadian Pacific Company would like such

Digitized by Google

advice to be given and discussed at a public meeting. With reference to the revenue from the renewal fund, the whole question of that fund was the subject of an arrangement that was entered into between the Board and the committee headed by Mr. Smith. The result of that arrangement was that no further addition to the renewal fund, except the interest derived from the investments forming the fund, should be added to it after it had reached to £1,000,000. It is not £1,000,000 yet, although, to use a common phrase, it is "within measurable distance" of that amount. When we get to our million we will consider how the interest earned by the investments of the fund shall be disposed of with due regard to the interests of the shareholders. The only other observation I am led to make is with reference to something that was said by Mr. Herbert Smith about this £18,000. He said it is not going to be paid in dividends; but what I said was that we do not declare it now, because it is only an estimate. We mean, however, hereafter to apply it to the shareholders' benefit just as much as if we gave it now. I am sorry that we are obliged to reject the amendment of Mr. Smith, but I cannot put it, and I hope that he will withdraw it. [Voices: "Withdraw!"]

Mr. SMITH said he would take the Chairman's advice under the promise which had been made. He again asked that a detailed statement might be made in the accounts as to the cost of the investments of the renewal fund. Let the Directors take as their guide the information that was given by the Globe Company.

The CHAIRMAN said he thought he had in a great measure supplied the information asked for in stating what the price of the securities was at the present time.

The motion was then put in the usual way, and declared to be carried.

Mr. ABBOTT proposed, and Mr. THOMAS SMITH seconded, a vote of thanks to the Chairman and Directors. This having been unanimously agreed to,

The CHAIRMAN said: I am exceedingly obliged to you for your vote of thanks, which has been so constantly passed to us. I am particularly obliged on the present occasion, because I feel that there is a great deal which the shareholders have to bear, and which the Directors would not impose on them if they could help it.

The proceedings then terminated.

Cuba Submarine Telegraph Company.

The thirty-second ordinary general meeting of the shareholders in this Company was held on Wednesday last, at the Company's offices, 61, Old Broad-street, E.C., under the presidency of Mr. Joaquin de Mancha.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I have again the pleasure of meeting you with a very favourable report, and I think that on the face of it very little need be said. Our business seems to go on satisfactorily. Our income has increased a little, although not so much as I should have liked, because we have carried a great many more messages in this half year than we did in the corresponding six months. Those extra messages amount to over 2,000, and the increase in our receipts has been only £547. People are getting so clever in the matter of telegraphy now, that the messages do not amount to so much as they did before. The report is so full that I need not detain you by going through the figures. You will see that we have been able to add a very substantial amount to the reserve fund, namely, £4,500, which now brings it up to £71,000, ready for any emergency. But you must bear in mind that although there is that sum to the credit of the reserve fund we still have to pay a portion of the cost of the cable that we contracted for, and which is being paid off every year. The amount still to be paid is £21,000 odds, so that you may reckon that our reserve fund is actually £50,000. We hope that the cable will continue to work as it has hitherto done, and in that case we shall be free from this annual payment in the course of five or six years. The report is so favourable that I shall not detain you longer with more explanations, but simply move, "That the report and accounts now submitted be received and adopted."

Mr. LOW seconded the motion.

Mr. SQUIRE wished to know the amount that was annually paid out of the revenue towards wiping off the debt on the cable.

The CHAIRMAN replied that it constituted an annual charge of £3,750.

Mr. GRIFFITH expressed his great satisfaction with the favourable nature of the report and accounts. He desired, however, to suggest whether it would not be better to invest the reserve fund in stock of a more permanent character than those in which it was now locked up. He further wished to know whether the Spanish agency could not be dispensed with.

The CHAIRMAN, in reply, said that, with regard to the latter question, the Company, according to the terms of its concession, was bound to have an agent at Madrid. It was not, he might say, absolutely necessary, but still it was an understood thing, and, moreover, the Directors found that it was very useful to have an agency there. For example, the other day, when there was some talk about a cable being laid to the Antilles by a Spanish company, their agent in Madrid kept them posted up in all that took place on the subject. Therefore, he was sorry to say that the Directors would not be able to do away with the item of £200 which the agency cost them. As regarded their investments, he could only say that the whole of them were perfectly safe. Unfortunately, every now and then there was a slight diminution in the rate of interest given for their deposits at the bank, and it might be possible that in a year or two money would become so cheapened that it would be safer to invest the whole of their reserve in Consols instead of as now. But at present he thought it was advisable that they should get as much as they could out of their £71,000. As to the amount that they would require the reserve to reach, they had put the figure at £100,000, but whether they would stick at that amount he would not like to say. Cables did not last for ever, and the time might come when they would have to lay an extra cable, which would cost them between £40,000 and £50,000. Therefore their reserve should be employed not only to lay any new cable that might be required, but to give security to the shareholders and maintain their dividend of 8 per cent., which he hoped would continue for many years to come.

The motion was then unanimously agreed to.

The CHAIRMAN: The next resolution is, "That the following dividends be now declared for the half-year on the shares of the Company, viz, at the rate of 10 per cent. per annum, subject to income-tax, on the preference shares, and at the rate of 8 per cent. per annum, free of income-tax, on the ordinary shares, payable on and after to-morrow."

Mr. NEIL BANNATYNE: I second that.

The motion was put, and carried unanimously.

On the motion of Mr. Low, seconded by Mr. GREENWOOD, Mr. J. de Mancha was re-elected a Director of the Company.

The auditor, Mr. Thomas Greenwood, was also reappointed.

Mr. GRIFFITH proposed a vote of thanks to the Chairman and Directors, whose services to the Company he highly eulogised.

Mr. SQUIRE having seconded the motion, it was cordially passed.

The CHAIRMAN, in reply, expressed the thanks of himself and his colleagues, and said he wished they might be able to improve upon the present dividend. At any rate they hoped they would never have occasion to come before the shareholders with a smaller one than they did now. Their endeavour had been to do their work satisfactorily. It was not a very hard task that they had to perform, and they were so well assisted by their secretary and by their *employés* that they got through it with a great deal of satisfaction, and whilst he would again thank the shareholders for their approbation, he would like to move a vote of thanks to Mr. Scott and to their *employés* abroad for the efficient manner in which they performed their duties.

The motion, having been seconded by Mr. Low, was carried unanimously.

The SECRETARY briefly responded, and the proceedings terminated.

Globe Telegraph and Trust Company (Limited).

The fourteenth ordinary general meeting of this Company was held on Thursday last at Winchester House, 50, Old Broad-street, under the presidency of John Pender, Esq.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting, and the minutes of the last meeting, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen—I will, as usual, make some remarks upon the business of last year, and give you all the information that we possess as to the working of the Company's affairs. Our accounts show a diminished dividend this year, resulting from the continuance of the 6d. tariff for the Atlantic cable companies in which we hold largely stocks and shares. In 1885 we received from this source £38,467, when we paid 4½ per cent. on our ordinary shares; in 1886 we received from this source £20,046, when we paid 3⅝ per cent.; in the financial year just ended we have only received £6,685, and our dividend is 2⅜ per cent. From the Eastern and the Eastern Extension Companies we received £92,029 in 1886, while in the present year we have had but £82,028. The diminution in the dividends above mentioned accounts generally for the falling off in the dividend on our ordinary shares, the diminiuton in the case of the two last named companies arising from the reduction of the tariffs forced on them by the Berlin Conference. This Company is the barometer of telegraph companies generally. It is low now, but I am sanguine that we shall see a change before long. The average dividend on the ordinary shares during the last 14 years of our existence has been a little over 4¼ per cent., and our preference dividend has, of course, always been maintained at 6 per cent., or an average on both classes of shares of over 5¼ per cent. You observe in the report what is said about the Direct Spanish Company. We have received the accumulated dividend of £2. 10s. a share, or something like £1,500, and this has been carried to our revenue account. The capital of that company was reduced by order of the High Court of Chancery to one-half its nomial value, and we look to steady dividends in future from that direction. The German Union Company are earning a fair dividend of 6 per cent.; the Indo-European Company are returning something like 11¼ per cent. on our purchase price; the London Platino Company are doing better; and the Construction Company paid their usual dividend of 20 per cent. I may mention as evidence of the public appreciation of the utility of the Globe Company that while the market value of the Globe holding is about 3¼ millions sterling the market value of the Globe shares issued against them is about three and a half millions, or 4 per cent. higher. I have shown you exactly the reason of the fall in our dividend—that fall mainly arising from the sixpenny tariff that is still in force with the Atlantic companies in which we are interested. You may naturally ask me if I can give you any information on the war of rates. All the information I can give you is this—that I believe parties on the other side who are largely interested in the land lines in America, and who are also interested in the submarine system, have this thing in hand very much at this moment. What the result may be it is difficult for anyone to say. I do not know that they themselves know, excepting that they are fully aware that, although the present sixpenny rate is developing the traffic steadily and largely, it is very doubtful if that rate will ever pay a large dividend. But I would ask you, as I have asked all those who are interested in Atlantic cables, to be patient. I do believe that the men of business connected with the system, even on the other side, realise the fact that the present business is bad, and as they have it in

Digitized by Google

sonally, and on behalf of my colleagues, not to give us a half confidence. We are doing all we can. We are endeavouring to economise in every way, and we hope the continuance of our policy will enable us to pay you, if not a large dividend, at all events a satisfactory one. With these observations I leave the matter in your hands, and I beg to move "That the report of the Directors and the accompanying statement of accounts to the 30th June, 1887, submitted to this meeting, be, and the same are hereby, received and adopted."

The Marquis of TWEEDDALE formally seconded the motion.

Mr. THOMAS SMITH (York) said he would support the adoption of part of the report, but he could not approve of the whole of it. He agreed with the Chairman's remarks as to the 6d. tariff; and the improvement in the traffics compared with the corresponding period of last year was very encouraging, and showed, to his mind, that the 6d. rate was an increasing success. For four months of the corresponding period of 1886 the 1s 8d. tariff was in force, as against 6d. in the whole of the past half year. The December half year they always considered, as the Chairman had said, the better half year, and in that half year they brought forward a balance of £2,423, leaving the net takings for the six months £87,384, compared with £100,534 in the six months now under review—to the 30th ult. In making that comparison, it must be remembered that they brought forward not a farthing in the half year just closed. After what the Chairman had said, he thought they might look forward with confidence to the coming half year, the best half of the year. He believed that they would consider with him that the sixpenny rate was progressing very satisfactorily, and that they had nothing to do but to sit still and work at it. In his opinion the future policy of the Company must be based on the 6d. tariff. Let them give it two or three years' trial. They would suffer from the want of dividend during that period; but he was quite willing, though a large shareholder, to forego his dividend for the present—that was, if the Directors would be fair towards them and divide what the Company earned. He did not agree with the Directors' policy as regarded the third paragraph of the report. At the last meeting the Chairman asked the shareholders for their patience, forbearance, and support, and he (the speaker) thought they had granted that request right loyally. Taking that into consideration, and the fact that nothing had been brought into last half year's account, he thought the Directors should have made the dividend on the ordinary stock 10s. per cent. and on the preferred stock £1 per cent. After the shareholders had suffered as they had, the Directors ought to meet them in the most liberal way, instead of proposing to carry forward a balance to the next half year of 50 per cent. of the net earnings of the last six months. Such a proposal he regarded as preposterous. And what were they carrying it forward for, seeing that they had £84,500 uninvested? He did not think it could be said that there was any shortness of money, with £84,000 doing nothing, and for which they had received £165 as interest. At the meeting last February, too, they were promised a detailed list of the investments.

The CHAIRMAN: Have you not got it in the report?

Mr. SMITH said he did not consider it a detailed statement, such as that given by Mr. Pender in the case of the Globe Telegraph Company. There was an item of £13,000 given as "other securities." Was that a detailed statement? Such a statement would only have to be done once, and it would really cause practically no trouble. He was glad to hear the Chairman speak about economy, but he could find no evidence of it in the accounts. In conclusion he moved as an amendment, "That the report be adopted, with the exception of the part of paragraph 3 which states that £18,323. 6s. 8d. be carried forward, and in lieu thereof that a dividend of 10s. per cent. be paid on the ordinary stock and 20s. per cent. on the preferred stock."

Mr. C. E. DAVISON seconded the amendment. The Directors must be aware that for a long time the shareholders had suffered from the want of dividends, and it was only right that, instead of £17,500 being now distributed, £35,000 should be divided among them, which would be the effect of carrying Mr. Smith's amendment, and which he urged the Directors to support.

The CHAIRMAN: I am not now going to answer Mr. Smith's observations, but I wish to say a few words about his amendment, as to which it would be perfectly useless and a waste of your time to have any discussion. I am precluded from putting it to the meeting by the Articles of Association. The shareholders cannot declare any larger dividend than that recommended by the Directors, and I should be forfeiting all claims to your confidence, and should be violating my duty if I put this amendment. I have the greatest possible sympathy with the shareholders. The fact is that this is an interim dividend. We retain this fund in our hands, but it is only an estimated surplus. It should be remembered that we are engaged in litigation with the French Company, and that we have at this moment a very expensive repairing expedition going out. We may require money for that, and at all events we have to the best of our judgment done what we thought was for the true interests of the shareholders in declaring this interim dividend, with the prospect that during the year we shall be able to give them something more.

Mr. WILLIAM ABBOTT said he had been very pleased to find Mr. Smith—a gentleman whose remarks at the meetings were deserving of every respect—so strong an advocate of supporting the Board in the policy they had adopted respecting the 6d. tariff. He himself at the last meeting had not agreed with that policy, because he had thought it desirable that some arrangement should be made by which the tariff should be raised to 1s. He had, however, completely altered his opinion, for the 6d. tariff did not suit their competitors at all. He thought they should continue the tariff, and wait and see the result. At that meeting he was particularly desirous that they should give a unanimous support to the Directors. He did not think the detailed information respecting the cost of the securities of the renewal fund was necessary, and what he himself admired about the report was its simplicity. They had securities valued at £882,000, with £84,000 uninvested. He thought it would be very satisfactory if they could be told whether the present market price of the £882,000 was in excess of the actual cost price of the securities. He begged the Directors to invest nothing further in the Canadian Pacific Railway Company.

The CHAIRMAN: It is a first mortgage.

Mr. ABBOTT said he had no faith in the Canadian Pacific Company. He was glad to see the legal expenses so small, and astonished to see Mr. Burt looking so well notwithstanding. He regretted that Mr. Smith had spoiled his statement by the amendment which he had proposed, and he thought that they should on that occasion show their competitors that they were "full of fight." He would be sorry to see distributed the £18,000 which the Directors in the report had suggested should be carried forward.

Mr. GRIFFITH said he considered that the argument adduced by Mr. Smith in support of his amendment was unanswerable. He maintained that the £84,000 referred to ought to have been invested to produce 3 per cent. at least. He entirely agreed with Mr. Smith. As to the amendment, the Chairman took a very restricted view of what the Articles of Association provided. They could put the amendment in this way—that they would not receive the report, that they would send it back, and that unless the Directors would declare the extra dividend which Mr. Smith proposed, they would not pass the report. Remembering the additional expense involved by the increased work that had to be done with a sixpenny tariff, he reckoned that they would have to earn four times the amount they had earned with the 1s. 8d. tariff before they could even attain the wretched position they were in with the higher tariff. He supported the amendment. The time had come when the Articles of Association should be altered.

Mr. JOHN NEWTON contended that the revenue earned by the reserve fund ought to be added to the general revenue of the Company, and not put to the fund.

Mr. HERBERT SMITH (Gray's Inn) maintained that it was unnecessary to carry forward the sum of £18 000 as proposed in the report.

Mr. HUMPHREYS wished to know why it was that the £84,000 had not been invested. He viewed the report in an unfavourable light, and he believed that the reduction in the tariff from 1s. 8d. to 6d. was an act of temper, the whole circumstances of the case not having been taken into consideration.

The CHAIRMAN: I regret very much that we have not the admiration for our report of the gentleman who has just sat down, but I think he takes rather a prejudiced view of the conduct of the Board, because he says that the adoption of a 6d. tariff was an act of temper. I can only say that so far from being an act of temper, when one commits an act under the influence of temper one acts hastily, but I never, since I have been on the Board—now for a good many years—remember any act that was taken with greater deliberation, more circumspection, and more consideration of all the circumstances of the case. The gentleman has also said that the rate would never rise beyond 6d. That view is certainly not derived from any observation I have made, for I guarded myself most carefully in saying that it was a low rate we went in for with a certain object, and that we can never bind ourselves to any particular rate as one we would arrive at. So much for Mr. Humphries. I now proceed to answer as well as I can the different observations made. Mr. Smith took occasion to animadvert on the amount of the dividend, and said it might have been 10s. per cent. He is quite right. It might have been 10s. per cent; but had we declared a 10s. dividend we should have divided up very closely on a balance which was only an estimated balance. I wish the stockholders to remember that this is not the final dividend. This is merely an interim dividend. You will, I hope, receive another and I trust a larger dividend next quarter.

A SHAREHOLDER: You told us that six months ago.

The CHAIRMAN: I do not pretend to infallibility, and if I did venture to prophesy I think it probable that I might have been incorrect. But still I had not the same ground then as I have now, because we have now, so far as an estimate goes, the money in hand, and we shall pay up as closely as possible in the next half year. Mr. Smith and some other gentlemen made some observations about the uninvested balance of the reserve fund. That balance is a sum which is probably not yet paid. Another portion of it is a sum which we shall have to pay in the course of a few days for the expense of the repairs; and now I put it to any of those gentlemen—I ask Mr. Abbott, as a practical man, does he think it would be wise for us as directors to invest money, incurring the expense of stamps and brokerage, which we should have to pay in two or three months?

Mr. ABBOTT: You must pay the broker.

The CHAIRMAN: We have sent out 300 miles of cable, which has to be paid for. It is really to save the money of the Company that we do not invest this sum. Then there is a small amount of £13 000 of which Mr. Smith made a great deal in point of argument. I wonder if Mr. Smith has ever read such a thing as the account of a charitable subscription, where a number of small sums are put down under one total. This £13,000 is put down here on the same principle. They are small investments not worth fully mentioning; but if Mr. Smith has the least curiosity he really only has to go to the offices of the Company and Mr. Wells will tell him.

Mr. SMITH said that he wanted the information not merely for himself, but for the benefit of all the shareholders. They could not all go to the offices for the information.

The CHAIRMAN: I think if you get the information respecting £382,000 it is taking rather a microscopic view of things to want the details about £13,000. Mr. Abbott asked what is the total value of the investments to-day. As nearly as we can calculate, taking the middle value, the securities are worth about £25,000 more than they cost us. As to the Canadian Pacific Railway, it was very good advice—[Mr. ABBOTT: It was only a hint]—given by a stockbroker to an investor who had come to consult him; but I do not think the Canadian Pacific Compnay would like such

advice to be given and discussed at a public meeting. With reference to the revenue from the renewal fund, the whole question of that fund was the subject of an arrangement that was entered into between the Board and the committee headed by Mr. Smith. The result of that arrangement was that no further addition to the renewal fund, except the interest derived from the investments forming the fund, should be added to it after it had reached to £1,000,000. It is not £1,000,000 yet, although, to use a common phrase, it is "within measurable distance" of that amount. When we get to our million we will consider how the interest earned by the investments of the fund shall be disposed of with due regard to the interests of the shareholders. The only other observation I am led to make is with reference to something that was said by Mr. Herbert Smith about this £18,000. He said it is not going to be paid in dividends; but what I said was that we do not declare it now, because it is only an estimate. We mean, however, hereafter to apply it to the shareholders' benefit just as much as if we gave it now. I am sorry that we are obliged to reject the amendment of Mr. Smith, but I cannot put it, and I hope that he will withdraw it. [Voices: "Withdraw!"]

Mr. SMITH said he would take the Chairman's advice under the promise which had been made. He again asked that a detailed statement might be made in the accounts as to the cost of the investments of the renewal fund. Let the Directors take as their guide the information that was given by the Globe Company.

The CHAIRMAN said he thought he had in a great measure supplied the information asked for in stating what the price of the securities was at the present time.

The motion was then put in the usual way, and declared to be carried.

Mr. ABBOTT proposed, and Mr. THOMAS SMITH seconded, a vote of thanks to the Chairman and Directors. This having been unanimously agreed to,

The CHAIRMAN said: I am exceedingly obliged to you for your vote of thanks, which has been so constantly passed to us. I am particularly obliged on the present occasion, because I feel that there is a great deal which the shareholders have to bear, and which the Directors would not impose on them if they could help it.

The proceedings then terminated.

Cuba Submarine Telegraph Company.

The thirty-second ordinary general meeting of the shareholders in this Company was held on Wednesday last, at the Company's offices, 61, Old Broad-street, E.C., under the presidency of Mr. Joaquin de Mancha.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I have again the pleasure of meeting you with a very favourable report, and I think that on the face of it very little need be said. Our business seems to go on satisfactorily. Our income has increased a little, although not so much as I should have liked, because we have carried a great many more messages in this half year than we did in the corresponding six months. Those extra messages amount to over 2,000, and the increase in our receipts has been only £547. People are getting so clever in the matter of telegraphy now, that the messages do not amount to so much as they did before. The report is so full that I need not detain you by going through the figures. You will see that we have been able to add a very substantial amount to the reserve fund, namely, £4,500, which now brings it up to £71.000, ready for any emergency. But you must bear in mind that although there is that sum to the credit of the reserve fund we still have to pay a portion of the cost of the cable that we contracted for, and which is being paid off every year. The amount still to be paid is £21,000 odds, so that you may reckon that our reserve fund is actually £50,000. We hope that the cable will continue to work as it has hitherto done, and in that case we shall be free from this annual payment in the course of five or six years. The report is so favourable that I shall not detain you longer with more explanations, but simply move, "That the report and accounts now submitted be received and adopted."

Mr. LOW seconded the motion.

Mr. SQUIRE wished to know the amount that was annually paid out of the revenue towards wiping off the debt on the cable.

The CHAIRMAN replied that it constituted an annual charge of £3,750.

Mr. GRIFFITH expressed his great satisfaction with the favourable nature of the report and accounts. He desired, however, to suggest whether it would not be better to invest the reserve fund in stock of a more permanent character than those in which it was now locked up. He further wished to know whether the Spanish agency could not be dispensed with.

The CHAIRMAN, in reply, said that, with regard to the latter question, the Company, according to the terms of its concession, was bound to have an agent at Madrid. It was not, he might say, absolutely necessary, but still it was an understood thing, and, moreover, the Directors found that it was very useful to have an agency there. For example, the other day, when there was some talk about a cable being laid to the Antilles by a Spanish company, their agent in Madrid kept them posted up in all that took place on the subject. Therefore, he was sorry to say that the Directors would not be able to do away with the item of £200 which the agency cost them. As regarded their investments, he could only say that the whole of them were perfectly safe. Unfortunately, every now and then there was a slight diminution in the rate of interest given for their deposits at the bank, and it might be possible that in a year or two money would become so cheapened that it would be safer to invest the whole of their reserve in Consols instead of as now. But at present he thought it was advisable that they should get as much as they could out of their £71,000. As to the amount that they would require the reserve to reach, they had put the figure at £100,000, but whether they would stick at that amount he would not like to say. Cables did not last for ever, and the time might come when they would have to lay an extra cable, which would cost them between £40,000 and £50,000. Therefore their reserve should be employed not only to lay any new cable that might be required, but to give security to the shareholders and maintain their dividend of 8 per cent., which he hoped would continue for many years to come.

The motion was then unanimously agreed to.

The CHAIRMAN: The next resolution is, "That the following dividends be now declared for the half-year on the shares of the Company, viz, at the rate of 10 per cent. per annum, subject to income-tax, on the preference shares, and at the rate of 8 per cent. per annum, free of income-tax, on the ordinary shares, payable on and after to-morrow."

Mr. NEIL BANNATYNE: I second that

The motion was put, and carried unanimously.

On the motion of Mr. LOW, seconded by Mr. GREENWOOD, Mr. J. de Mancha was re-elected a Director of the Company.

The auditor, Mr. Thomas Greenwood, was also reappointed.

Mr. GRIFFITH proposed a vote of thanks to the Chairman and Directors, whose services to the Company he highly eulogised.

Mr. SQUIRE having seconded the motion, it was cordially passed.

The CHAIRMAN, in reply, expressed the thanks of himself and his colleagues, and said he wished they might be able to improve upon the present dividend. At any rate they hoped they would never have occasion to come before the shareholders with a smaller one than they did now. Their endeavour had been to do their work satisfactorily. It was not a very hard task that they had to perform, and they were so well assisted by their secretary and by their *employés* that they got through it with a great deal of satisfaction, and whilst he would again thank the shareholders for their approbation, he would like to move a vote of thanks to Mr. Scott and to their *employés* abroad for the efficient manner in which they performed their duties.

The motion, having been seconded by Mr. LOW, was carried unanimously.

The SECRETARY briefly responded, and the proceedings terminated.

Globe Telegraph and Trust Company (Limited).

The fourteenth ordinary general meeting of this Company was held on Thursday last at Winchester House, 50, Old Broad-street, under the presidency of John Pender, Esq.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting, and the minutes of the last meeting, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen—I will, as usual, make some remarks upon the business of last year, and give you all the information that we possess as to the working of the Company's affairs. Our accounts show a diminished dividend this year, resulting from the continuance of the 6d. tariff for the Atlantic cable companies in which we hold largely stocks and shares. In 1885 we received from this source £38,467, when we paid 4½ per cent. on our ordinary shares; in 1886 we received from this source £20,046, when we paid 3⅝ per cent.; in the financial year just ended we have only received £6,685, and our dividend is 2⅜ per cent. From the Eastern and the Eastern Extension Companies we received £92,029 in 1886, while in the present year we have had but £82,028. The diminution in the dividends above mentioned accounts generally for the falling off in the dividend on our ordinary shares, the diminiuton in the case of the two last named companies arising from the reduction of the tariffs forced on them by the Berlin Conference. This Company is the barometer of telegraph companies generally. It is low now, but I am sanguine that we shall see a change before long. The average dividend on the ordinary shares during the last 14 years of our existence has been a little over 4¼ per cent., and our preference dividend has, of course, always been maintained at 6 per cent., or an average on both classes of shares of over 5¼ per cent. You observe in the report what is said about the Direct Spanish Company. We have received the accumulated dividend of £2. 10s. a share, or something like £1,500, and this has been carried to our revenue account. The capital of that company was reduced by order of the High Court of Chancery to one-half its nomial value, and we look to steady dividends in future from that direction. The German Union Company are earning a fair dividend of 6 per cent.; the Indo-European Company are returning something like 11¼ per cent. on our purchase price; the London Platino Company are doing better; and the Construction Company paid their usual dividend of 20 per cent. I may mention as evidence of the public appreciation of the utility of the Globe Company that while the market value of the Globe holding is about 3¼ millions sterling the market value of the Globe shares issued against them is about three and a half millions, or 4 per cent. higher. I have shown you exactly the reason of the fall in our dividend—that fall mainly arising from the sixpenny tariff that is still in force with the Atlantic companies in which we are interested. You may naturally ask me if I can give you any information on the war of rates. All the information I can give you is this—that I believe parties on the other side who are largely interested in the land lines in America, and who are also interested in the submarine system, have this thing in hand very much at this moment. What the result may be it is difficult for anyone to say. I do not know that they themselves know, excepting that they are fully aware that, although the present sixpenny rate is developing the traffic steadily and largely, it is very doubtful if that rate will ever pay a large dividend. But I would ask you, as I have asked all those who are interested in Atlantic cables, to be patient. I do believe that the men of business connected with the system, even on the other side, realise the fact that the present business is bad, and as they have it in

Digitized by Google

their power to make the alteration more than we have on this side, I am hopeful that before many months pass over we shall see the war of rates at an end. At all events, the companies here are doing their best, and I think we are bound to support them, because, after all, we are very large shareholders in the Atlantic and other companies. We are bound to support them in this sense, that there has been a great deal said about low rates enormously increasing the traffic and consequently the revenue. I believe that low rates must eventually increase the revenue, but the cable system is a peculiar system. We can only carry a certain number of words on a cable, and if the 6d. rate does not pay the cable when it is full, of course we cannot expect any extension of traffic will give us any increased return. It would require more cables, and therefore more capital would be required to lay those cables. However, I think it is right, now that we are dealing with a sixpenny tariff, that we should exhaust it to the fullest point, and that a few months more will not be badly spent in testing how far this sixpenny tariff is going to be developed. The other fall which I referred to was the lowering of the rates arising from what was done at the Berlin Conference. When I last had the pleasure of addressing you twelve months ago we had just begun the lower rates which were then forced upon us. Those lower rates involved something like a loss of £100,000. For the first few months after the rates were reduced we saw very little response, but I am glad to say that we are almost day by day recouping the loss, and by the time I meet you next year I believe I shall be able to say that that loss has been recouped. That is one of the bright sides of the picture, and if I can add at the same time that we have got a reasonable rate for our Atlantic system, with our vast interest in that system, we shall be able to show you a very much better dividend than we can show you to-day. I have given you probably all the information I can give you excepting this, that this Globe Company holds interests in every submarine system—(A Voice: Except the Commercial)—except the Commercial, which is a private company; but I would not be astonished if before very long you see the Commercial Company's interest more or less connected with the Globe interest. What, however, I was going to say was this—that the growth of submarine telegraphs is really enormous, and they are conferring benefits not only at home but throughout our Colonies, and, in fact, in every part of the civilised world. As I said at a public gathering last night, the mileage of submarine cables within the last twenty years has risen from about 2,000 to 115,000 miles. That shows that the system of submarine telegraphy is becoming a vast interest, and as the Globe Company will more or less be dependent upon that system, and as that system is growing, I have no doubt that the Globe Company must eventually benefit through that growth. I think that that is pretty much all that I have to tell you. The different cables in which we are interested are all working fairly well. As to those of our opponents—the other Atlantic cables—two of them are interrupted, and that fact contributes largely to the traffic of those that remain. As, however, I have said, the 6d. rate, while doing good in one direction, I am afraid does not do much good towards paying a dividend. I now beg to move "That the report and accounts for the year ended 18th July, 1887, submitted to this meeting, be and they are hereby received and adopted, and that dividends be now declared payable on and after this day as follows—namely, 3s. per share on the preference shares, making with previous quarterly dividends a total dividend of 6 per cent. on the preference shares, less income-tax, and of 2s. 3d. per share net on the ordinary shares, making with previous distributions a total payment for the same period of £2. 7s. 6d. per cent. per annum on the ordinary shares."

Sir DANIEL GOOCH, Bart., seconded the motion.

Mr. CROOKS asked whether it would not be advisable to get rid of a bad bargain, and dispose of the interest held by them in the Atlantic cables to the amount of over £1,000,000. Why should they continue to carry a heavy burden like that?

The CHAIRMAN: You would not sell stock at a time when it is depressed.

Mr. CROOKS: If I have a bad tenant I do not see why I should keep him. I should get rid of him, and obtain a tenant who would pay me.

The CHAIRMAN: But always take your goods to the best market. You could not take them to a worse market than at the present time, and, more than that, I do not think you could get a customer.

Mr. CROOKS said that if he had invested £40,000 in anything which brought him no return, he would be disposed to sell the investment for half its value, and invest the £20,000 and get some interest on the lower amount.

The CHAIRMAN: I think you must trust your Directors in the management of this business. We have told you exactly the circumstances which have arisen to reduce the Atlantic tariff from 2s. to 6d. I have told you very distinctly, I think, that the 6d. rate is not likely to continue very much longer, and if we revert to a higher rate we shall be able to pay a very much higher dividend. Therefore, with such a prospect before us, I think it would be very foolish indeed if we parted with a single pound's worth of our property.

Mr. CROOKS pointed out that the shareholders, under the existing state of things, had been heavy sufferers for the last eighteen months or two years.

The CHAIRMAN: It is not quite a bed of roses for Directors when a war of rates is going on.

Mr. CROOKS: But the poor shareholders have to suffer.

The CHAIRMAN: It so happens that in this case we are poor shareholders, too. There is nothing so unpleasant to the Directors as to come before you and propose such a poor dividend. In answer to Mr. John Brown the Chairman added: I have not seen the paragraph that you speak of in *The Times* of this morning, but I think I know pretty well what that paragraph must be. I think I have stated to you that there are negotiations going on which I hope will result in making a change for the better. I am not prepared—because I do not know myself—to state what the negotiations are, but I mentioned, I think, that there are men of business largely interested in these negotiations who know at the present moment that it is a bad state of things that exists, and that the sooner they improve it the better. I am therefore hopeful that before a very long period we shall get out of these bad rates.

A SHAREHOLDER said that on the previous day Lord Monck, at the meeting of the Anglo-American Telegraph Company, had stated that there were no negotiations going on.

The CHAIRMAN: I think you must have misunderstood him, for I was present. What Lord Monck said was, what I have said, that there are negotiations going on in America and not in England, and therefore that we do not know what is the nature of the negotiations. There are large land lines in America that belong to the Western Union Company, and there is a competing system, and when this question is settled with regard to the land lines there will be a settlement also with respect to the submarine cable system.

Mr. MASON said that the paragraph in *The Times* of that day, to which reference had been made, had been cabled from Philadelphia on the previous day, and was as follows:—"The negotiations between the rival Atlantic cable companies are reported to be making progress. The result may be a termination of the 'cable war,' and the advancing of rates to 40c., and probably even 60c., per word."

The CHAIRMAN: All I can say in regard to that paragraph and newspaper paragraphs generally is that until I know absolutely myself I do not pay very much attention to newspaper paragraphs. I am receiving every day telegrams from America as to what is said in one paper and what is said in another, both at Boston, Philadelphia, and New York. I sometimes ask whether there is any truth in these statements, and generally the answer is "No," or, like the other day, "Very exaggerated."

Mr. JOHN NEWTON asked what was being done with respect to the French Cable Company. He thought the shareholders would be very glad if the Directors would increase the interest of the Company in the French Company, so that they could then teach that Company a lesson in fair play and justice, and go to their meetings with sufficient influence to command the position. The Globe Company ought to be very much more powerful than it was to stop competition. One mistake they had made was in having gone into business without having sufficient capital to control the telegraph systems of the world. They could, he held, have occupied that position if the original intention had been carried out. He would be glad to hear that the Directors intended to get control of the French Company, which had broken its contract with the English Companies. On the question of the cable war, he was perfectly satisfied that negotiations were going on, and with the support of the Directors of the English Companies. He hoped that no settlement would be made unless it settled for some time the question of what was a paying rate.

The CHAIRMAN: Hear, hear.

Mr. NEWTON: If the 6d. rate were continued for a few months more, probably they would be able to say, and to say with authority, what was the exact result.

The CHAIRMAN, in reply, said: I think Mr. Newton has made one point, and that point is that we should now, as far as it is within human power to do it, make a permanent settlement of the rate that will give a fair return to the shareholders. I think it is for that reason that I ask you to forbear a little longer. The question of rates should be settled, and the rate should be such as would give a fair return to the shareholders, full justice to those who use the telegraph, and no encouragement whatever to competitors to bring in fresh cables. That is the policy we have before us, and that, I hope, we shall keep steadily in sight during these negotiations.

A SHAREHOLDER asked what rate the Chairman thought would give a fair return to the shareholders.

The CHAIRMAN: You must not ask me questions of that kind.

A SHAREHOLDER: What does the Commercial Company charge?

The CHAIRMAN: Their rate is 1s. They have gone on at 1s. They made a bargain that all those that stood by them and paid 1s. would, if they went above 1s. 8d., be refunded the difference between 1s. and 6d. That has gone on for a considerable time. When they started at 1s. 8d., which was a reduction of 4d. on the then existing tariff, they got a very large proportion of the traffic from us. I think, however, at the present time they are in the most unsatisfactory position, and I believe they will be quite as anxious as we are to arrive at an arrangement, though I do not say that we are particularly anxious on the point.

Mr. NEWTON asked whether the Directors saw their way to increase their interest in the French Company.

The CHAIRMAN: The French Company is in a very peculiar position as to the shares. If we bought a large number of the shares we should not know how to use them. We should have to put them into the hands of a variety of people. That company is in a very unfortunate position at the present time. Their cable is broken. They are out of the pool—at least, they say they are out, and they are now in a sort of helpless condition. The shares of the French Company within the last three or four months have fallen from something like 110fr. to 80 or 90fr., and the fall is still, I hear, going on. I think that our position is very fortunate compared with theirs.

The resolution was then put and carried.

On the motion of the CHAIRMAN, seconded by the Marquis of TWEEDDALE, Mr. William Ford and Sir Daniel Gooch, Bart., were re-elected to their seats at the Board. Subsequently, on the motion of Mr. JACKSON, seconded by Mr. STOCKDALE, Mr. John G. Griffiths, F.C.A., and Mr. William Griffith, B.A., were re-elected auditors of the Company.

Mr. GRIFFITH then proposed a vote of thanks to the Chairman and Directors. He thought the shareholders were very fortunate in having as Chairman of the Company a gentleman whom he regarded as the chief authority on telegraph questions. In times past the shareholders had

Digitized by Google

received good dividends from the Company, and though at present the dividend was not so large as usual, the reason which had been given by the Chairman must be looked upon as sound and satisfactory. The Chairman had given the shareholders all the information they had required, and most valuable information.

Mr. JACKSON seconded the motion, which was carried unanimously.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself, I return you sincere thanks for the renewed expression of your confidence in us. We are watching very closely all that is going on in the Atlantic cable system at the present time, and, as we are very large shareholders in all the companies, you may depend that if we saw anything going on that was contrary to your interests we should be the first to endeavour to stop it. As long as we sit on this side of the table it will be our interest to protect your interests, and to pay you the best dividend we can.

The proceedings then terminated.

CITY NOTES, &c.

EASTERN TELEGRAPH COMPANY.—This company announce that they will, on and after the 2nd August, pay the Five per Cent. Debentures terminable on that day at the Banking House of Messrs. Glyn, Mills, Currie and Co, 67, Lombard-street, London, with the final coupon of £2. 10s. The debentures to be lodged at the bankers two clear days for examination before payment.

THE EASTERN EXTENSION, AUSTRALASIAN, AND CHINA TELEGRAPH COMPANY.—This company notify that the coupon on their Six per Cent. Debentures due August 1st will be paid after that date at the Consolidated Bank, 52, Threadneedle-street, E.C. The coupon must be left at the bank three clear days for examination.

NATIONAL TELEPHONE COMPANY.—The directors announce a dividend for the six months ending 30th June last at the rate of 6 per cent per annum on the first and second preference shares, and at the rate of 4 per cent. per annum on the ordinary shares, as against 3½ per cent. for the corresponding period last year. Of the remaining profits the sum of £1,500 is to be added to the reserve fund, and the balance of £214 carried forward. The unaccrued revenue carried forward to the credit of next account amounts to £49,525, as against £43,985 carried forward last year.

WOODHOUSE AND RAWSON.—It will be seen that the business of Messrs. Woodhouse and Rawson is to be turned into a limited company, with a capital of £200,000. The company is to acquire the business of this well known firm, the stock-in-trade, patents, shares in subsidiary companies, goodwill and other assets. It will be seen from the prospectus, which will be found in our advertising columns, that the founders practically stake the whole of their acquired position and profits upon the future of the Company, pledging the whole value of their patents, and all future improvements thereon, licenses, agencies, options, and goodwill, as a guarantee for the payment of a cumulative dividend at the rate of 10 per cent. per annum on the capital now offered for subscription. The arrangement with reference to the founders' shares is of great importance to the ordinary shareholders, as it permits the declaration and payment of dividends out of the sales of patents or licenses Messrs. Woodhouse and Rawson were one of the first firms to devote themselves specially to electrical work, are contractors to the Admiralty, War Office, Metropolitan Board of Works, the Royal Courts of Justice, and other public departments; they have also done a large amount of work for many well-known establishments, such as the Lancashire and Yorkshire Railway, Messrs. Guinness and Co., Messrs. James Shoolbred and Co., the Stock Exchange, &c., and have obtained numerous medals, certificates, &c., at the principal exhibitions. The business is to be taken over as a going concern, the management remaining exactly as it now stands, with the exception that Mr. F. L. Rawson will have coupled with him as managing director Mr. Hoster, the inventor of the postal stamping machine and the Garry-Hoster rifle, whose thorough knowledge of Continental business will be of great assistance in the foreign department, to which he has already been attending for some months past. The other directors besides Sir John Stokes are Mr. Kincaid, who will take charge of the electrical railway and tramway department, and Mr. Lambert, who was a partner in the firm of Humber and Co., the bicycle manufacturers, before he turned his business into a company. We trust the development of the company will continue as satisfactory in the future as the progress of the firm has in the past; and this is to be expected, especially as it will be under the same energetic management.

NEW COMPANIES REGISTERED.

CROYDON AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED). Registered by Edmund Dean, 37, Walbrook, E.C., with a capital of £20,000 in shares of £5 each. Object, to carry on the business of electric engineers and to supply the parish of Croydon with electric light, electric heat, and electric power.

STANHOPE
PATENT ELECTRIC TELEPHONES.

NOTES.

BUCHAREST.—The Roumanian Government has announced the intention of undertaking the establishment of a telephone exchange at Bucharest.

EDISON AND SWAN V. SHIPPEY BROTHERS.—In another column will be found a report of the trial of the above action, which it will be seen resulted in favour of the plaintiffs.

THE INDIAN TELEGRAPH LINES.—The average time occupied in the transmission of messages from London to Calcutta by the lines of the Indo-European Telegraph Company is now one hour and ten minutes.

OPEN CONTRACT FOR ELECTRIC LIGHTING IN GERMANY.—On the 10th of September a contract will be made for lighting the town of Bremen by electricity. Particulars can be obtained from the Bureaukanzlei-fur-den, Zollanschloss, 219, Contrescaupe, Bremen.

ELECTRIC LIGHTING AT BURLINGTON HOUSE.—The Royal Society are about to extend the electric installation to a number of additional rooms. The work has been entrusted to Messrs. Drake and Gorham, by whom the installation was designed in the first instance.

PATENT LAW IN SWITZERLAND.—A poll recently taken in Switzerland has resulted in 190,000 votes for, and 56,000 against, an alteration in the law so as to give inventors better protection than they now enjoy. The Federal Government is thus empowered to enact a protecting law.

BRIGHTON.—A proposal is now before the Brighton Town Council to improve the lighting of the Marine Parade by the expenditure of an additional £563 per annum for gas. It is to be regretted that the Council do not see their way to place the contract in the hands of the local Electric Light Company.

THIRSK.—Proposals are invited for lighting the town of Thirsk with gas, oil, or electricity; seventy-two lights are required, to burn 1,100 hours per annum. Tenders are to be sent in by the 10th inst. to Mr. Z. Wright, clerk to the Inspectors, Thirsk, from whom also further particulars may be obtained.

THE BRUSSELS 1888 INTERNATIONAL EXHIBITION.—The electrical section of the International Exhibition, to be held next year at Brussels, is likely to prove one of very considerable interest and importance. In another column will be found the schedule under which prizes and medals will be awarded.

WIND-POWER.—The correspondent of a provincial contemporary is anxious to provide his house in the country with electric light. As only thirty lamps are required, he proposes to place a large vane or weathercock on the gable end of the house, and attach it to a vertical shaft from which the dynamo will be driven, storage cells being, of course, provided for use in calm weather.

NEW BOOKS.—We have received a copy of "Die Construction der Magnet-Elektrischen und Dynamo-Elektrischen Maschinen," by Von Gustav Glaser De Cew, edited by Dr. F. Auerbach, and published by A. Hartleben at Leipzig. The same publisher also sends us a copy of "Die Wirkungsgesetze der Dynamo-Elektrischen Maschinen," by Dr. F. Auerbach, of the University of Breslau.

ELECTRICAL COMMUNICATION WITH LIGHTSHIPS.—It is understood that the committee appointed by the Board of Trade to inquire into the desirability of electrical communication between light vessels and outlying lighthouses and the shore, with the special object of facilitating the saving of life at sea, have presented their report to the Board. It will be at once printed and circulated.

AN AMERICAN ELECTRIC LAUNCH.—The American electricians have been somewhat slow in turning their attention to the propulsion of boats by electricity, a circumstance which is no doubt accounted for by the fact that they have as yet but little experience with secondary batteries. An electric launch is, however, now being built in New York. The vessel will be 37ft. long, 7ft. wide, and 5ft. deep.

CHINESE TELEPHONES AND TELEGRAPHS.—The daily papers contain rumours to the effect that an American syndicate has obtained concessions from the Chinese Government giving it the exclusive right to construct railways, telegraph and telephone lines in certain parts of the Empire for a long period. We mentioned some weeks ago that certain American schemes were on foot in connection with the introduction of telephone lines in China.

MR. POPE ONCE MORE TO THE RESCUE.—Mr. Gilbert Pope has followed up the gallant achievement to which we referred last week by a feat of a similar character, in which, in the face of great difficulties, he succeeded in bringing ashore the body of a gentleman named Baldwin, an agent of the Duke of Devonshire, who had been seized with a fit whilst bathing at Lismore. Unfortunately, although rescued from the water, Mr. Baldwin did not recover, his death being attributed by the doctors to apoplexy.

NEW CABLE.—We understand that the new cable of the Eastern Telegraph Company has been successfully laid from Land's End to Lisbon and from Lisbon to Gibraltar, by the Telegraph Construction and Maintenance Company's ss. "Scotia." This cable is to be continued to Malta and Zante. It will be seen that this new cable provides a route for messages eastwards that touches at no foreign shore except Lisbon, and if any difficulty should arise with Portugal it will be easy to connect direct to Gibraltar.

TELEGRAPH INSULATORS.—In the House of Commons on Monday last Colonel Hughes-Hallett asked the Postmaster-General the price paid for the telegraph insulator manufactured by one particular firm, and what was the ordinary market value of this insulator? Mr. Raikes replied that the latest price paid by the Department for the insulator referred to in the first part of the hon. member's question is 10d., and as this kind of insulator is manufactured solely by the firm from whom they are obtained, 10d. may be taken as the ordinary market value.

NEW YORK.—The Thomson-Houston system is about to make a start in the City of New York, where hitherto the Brush and Weston systems have had a practical monopoly in arc lighting. Three companies have been formed to divide up New York City, and the orders given the Thomson-Houston Company for plant amount to no less than 2,250 lamps to start with, with prospective orders for double this number. The Edison Company have also just commenced to build a very large central incandescent lighting station further up the river, and it is rumoured that two more stations of the same size will shortly be undertaken in the same quarter.

ELECTRIC LIGHT FOR SEA FISHERIES.—Experiments are now being carried out in the Firth of Forth, on board the steamship "Tweeddale," on the use of the electric light for fishing at sea. The vessel has been fitted with an engine and dynamo, a 6,000 candle-power arc lamp, and some powerful incandescents, by Messrs. J. H. Perry and Co., of Liverpool. The incandescents were attached to the beam of the net, and

Digitized by Google

sunk to a depth of 40 or 50 fathoms. But although the glass globes employed were ⅜in. in thickness it was found that they were not strong enough to withstand the pressure, and after a short time the glass invariably gave way. It is intended to renew the experiments next week with stronger globes.

SIGNALLING BY ELECTRIC LIGHT IN THE FRENCH NAVY.—M. J. Le Baron, electrical engineer to the firm of A. de Meritens and Co., writes us as follows:—"Whilst I was far from Paris you have published in your issue of June 10th, a note on naval signals transmitted at night by means of incandescent lamps. I only beg to add that lamps are supplied by small alternate current magneto-electric machine running by hand and made by Baron de Meritens, whose largest magneto-electric machines have just been installed at St. Catherine (Isle of Wight) and Isle of May lighthouses (*The Electrician*, December 17th and 24th, 1886). The Italian Navy is also provided with same apparatus supplied by our firm, A. de Meritens and Co."

HORSE v. ELECTRIC TRACTION ON TRAM LINES.—The following facts and figures are eloquent in proof of the need for reform in the present system of horse traction on tram lines:—During the last six months sixty horses belonging to the North Metropolitan Tramways Company have died or had to be killed, and 101 have been sold as no longer fit for the service. The first-named represent a loss to the company of £2,152, and the "cast" horses were disposed of at a sacrifice of £3,238, making a total of £5,390 loss on the half-year. Last year, in the corresponding period, it was £5,587. The company possess close upon 3,000 horses. It is clear that the Electric Traction Syndicate should receive the warmest encouragement and support from the R.S.P.C.A.

THE INSTITUTION OF MECHANICAL ENGINEERS.—In another column will be found an abstract of an interesting paper by Mr. D. A. Stevenson, on "The Electric Lighthouse at the Isle of May," read at one of the meetings of the Institution of Mechanical Engineers which are being held this week at Edinburgh. In our next issue we shall print a paper read by Mr. W. Geipel, "On the Position and Prospects of Electricity as Applied to Engineering," which will be found to contain a comprehensive survey of the whole field of electrical engineering. The only remaining paper dealing with electrical subjects was one on "Electrical Machine Tools," read by Mr. F. J. Rowan, and which gave an account of the apparatus devised by Mr. C. E. Rowan, which was fully illustrated and described in our issue of 3rd June.

WOODHOUSE AND RAWSON (LIMITED).—It should be a sign of progress when a larger capital is required in a business, and we take it that the necessity for a larger capital is the principal reason for turning a flourishing firm into a company. As is well known to our readers, Messrs. Woodhouse and Rawson commenced business in the early days of the electric lighting industry, and no one will dispute the energy that has been thrown into the business—till the name is as well known as that of any interested in the industry. There is no doubt but that electrical work is growing, and will continue to grow, and that firms or companies that determine to give good workmanship and refuse business at an unremunerative figure, except when it is intended to be scamped, will find plenty to do in the near future. Some further particulars will be found at the end of the paper.

THE ELECTRIC LIGHTING ACT.—Mr. Hugh Watt has now placed the following notice of motion on the order book of the House of Commons:—"That the experience gained since the passage of the Electric Lighting Act of 1882 having demonstrated the impracticable provisions of that Act, no measure short of its repeal and the substituting thereof of legislation rendering it possible to supply electric light to the public with a fair prospect of remunerative returns will be of any benefit to the electric lighting industry, and as that Act has to a very large extent destroyed the growth of the industry in this country, and driven the export trade into American hands, it is desirable that the aforesaid Act be forthwith repealed, and those engaged in this new industry (which now employs nearly £50,000,000 of capital and over 50,000 workmen in America) be freed from the fetters of legislation which have proved of so disastrous a character."

ATMOSPHERIC ELECTRICITY.—Some instructive experiments on atmospheric electricity are described by Herr Nahrwold in *Wiedemann's Annalen*, No. 7. He thinks it established that the action of electricity from points on finely divided matter in the air does not electrify the air itself statically (indeed, that air and other gases probably cannot be statically electrified), but only dust particles in it. A glowing platinum wire sends out particles which diffuse in air that has been electrically freed from dust, making a fresh charge possible. Here, too, the electricity streaming from such wire does not statically electrify the air; but the charges which are observed as atmospheric electricity belong to fine non-gaseous particles given out by the wire, or already present in the air. An experiment is also adduced to show that at ordinary temperature negative electricity of high potential streams from solid conductors into atmospheric air more readily than from positive.

THE ELECTRIFICATION OF GASES BY IGNITED BODIES.—From investigations by J. Elster and H. Geitel the following facts have recently been determined:—"(1) The phenomenon that insulated conductors near an ignited body are electrically charged holds also for gases which have been freed from dust by filtration through glycerine wadding. (2) This holds also even when the rarefaction is raised to the extreme limits of a Crookes tube. (3) The electrification is positive for red heat, and all temperatures beyond in all gases as yet examined, with the exception of hydrogen, which at a high temperature has the opposite behaviour. (4) For air and carbonic acid the maximum of electrification is at a yellow heat. (5) The layer of gas which surrounds an incandescent body shows a different deportment as respects positive and negative electricity. That electricity whose sign is opposite that developed in the gas by ignition is most rapidly discharged."

THE BRITISH ASSOCIATION.—At the Manchester Town Hall, on Wednesday last, a meeting of the local general committee was held to receive the report of the executive committee of the British Association with reference to the approaching meeting in Manchester. Mr. Alderman Goldschmidt, who presided, said that the evidence already to hand indicated that this meeting would be a very remarkable one. The attendance of foreign members would be unprecedented both as regarded numbers and rank, and he had the privilege of announcing, as additions to the published list of very distinguished personages, the name of the Emperor of Brazil, who had been a member of the association since 1871, and was one of the wisest and most learned monarchs who ever sat upon a throne, and also that of a representative of the Congo Free State, who had been expressly nominated by the King of the Belgians. The report of the executive committee was read and adopted.

A REED TELEPHONE.—With the idea of obtaining more perfect articulation in the receiver, Mr. A. G. Safford, of Washington, has devised a telephone in which a number of sector-shaped reeds, of different widths and thicknesses, are put together so as to complete a circular disc, having a small

Digitized by Google

central aperture. The reeds are held by screws at their outer margins, and are free to vibrate independently. These reeds are timed to different rates of vibration, and each semi-tone of an entire octave of the diatonic scale is represented. Each reed has a magnet pole set underneath, and these poles project from a single core upon which the coil is wound. The idea is that every harmonic in the human voice shall find at least one portion of the diaphragm capable of responding to its rate of vibration. For the transmission of vocal or instrumental music with the least possible degradation, probably this instrument is better adapted than the ordinary form. Beyond this it seems impossible to say anything for the idea.

POROUS CELLS OF CORK.—The construction of porous cells appears to be receiving attention at the present time in several quarters. There is no doubt that in respect of weight and fragility clay cells present disadvantages which it is well worth while to seek to avoid. We mentioned last week the use of vulcanised fibre for this purpose; since then we learn that M. Stein, of Bonn, has succeeded in making porous cells of cork waste. The cork is first reduced to a finely pulverised form, and is then made up into a sort of stiff paste by the addition of naphthaline diluted with a certain quantity of water. Moulds of the required form are filled with the mixture, which is then dried at a gentle heat. A certain portion of the naphthaline is driven off and is recovered for further use. The cells thus made are extremely cheap, and weigh very little. They are also said to be both strong and durable, and to possess a suitable degree of porosity. In addition to these advantages, it is also said that the presence of the naphthaline prevents the formation of salts upon or within the walls of the cell.

THE LIGHTING OF THE VIENNA OPERA.—The electric lighting of the Vienna Opera House, which has been undertaken by the British and Continental Gas Association, was expected to have been completed by Sunday last, when the theatre was to have been re-opened. It was, however, found necessary to postpone the opening for a week, the work, which was only commenced six weeks ago, not being quite finished. The dynamos are of the Crompton vertical type with double horseshoe magnets, and give an output of 120 amperes at 600 volts. They are employed to charge in series five sets of batteries which discharge over independent circuits. The lighting of the stage is controlled by a special switch connected with both arc and incandescent lamps enclosed in globes of various colours, and the combinations are so arranged as to give the effects of daylight, dawn, sunset, the furious blaze of a conflagration, or pale silvery moonlight. It is anticipated that these effects will surpass anything of the kind hitherto attempted. To avoid any unnecessary disturbance of the walls, which are very handsomely decorated, it was found possible to make use, to a considerable extent, of the gaspipes as channels for the wiring.

TRANSFORMERS.—The question as to the best value to give to the periodic time of alternations of the current in a system of transformers is a somewhat complex one, inasmuch as the period cannot receive any adjustment without at the same time upsetting the conditions under which the dynamo is worked. It is, however, evident that a transformer having a wire core, can, other things being equal, be economically worked at a higher rate of alternation than one with a plate core. In practice there has been a tendency to reduce the number of alternations at first employed. The Gaulard-Gibbs transformers commenced with 150 alternations—a number which was probably arrived at merely because it happened to suit the available dynamos. Some later systems, in which plate cores are used, and for which special dynamos are supplied, run at 100 alternations. But, on the other hand, the Zipernowski-Déri system, which has a wire core, and which started at 80 alternations, has now, we understand, been reduced to the low figure of 50. It is obviously advantageous to keep the period as short as possible provided that the loss by Foucault currents in dynamos and transformers together does not exceed the economical limit.

LAMPS PER HORSE-POWER.—*Light, Heat, and Power* gives the following figures relating to the commercial efficiency of dynamos at different outputs. The first set of tests were made by our contemporary upon a 200-light machine built by a prominent company four years ago, and "using the most improved lamps now made by that company." In both this and the following test the lamps were kept up to 16 candle-power.

178	lights	required	24·4	H.-P.,	equals	7·3	lights	per H.-P.
91	,,	,,	14·36	,,	,,	6·34	,,	,,
45	,,	,,	9·08	,,	,,	4·96	,,	,,
5	,,	,,	4·79	,,	,,	1·04	,,	,,

Dynamos only, no lights, 3·07 H.-P.

The second set of tests were made upon a 400-light machine supplied by a younger company, and show a marked improvement in efficiency.

400	lights	required	40·89	H.-P.,	equals	9·98	lights	per H.-P.
300	,,	,,	30·82	,,	,,	9·70	,,	,,
200	,,	,,	20·91	,,	,,	9·5	,,	,,
100	,,	,,	12·28	,,	,,	8·1	,,	,,
50	,,	,,	7·75	,,	,,	6·4	,,	,,

Dynamos only, no lights, 3·78 H.-P.

NEWCASTLE-ON-TYNE.—At the Newcastle-on-Tyne Exhibition an incident occurred last week which is thus reported in a local journal:—"A singular accident occurred on Saturday with one of the electric lamps at the Newcastle Exhibition. One of the lamps had been lowered for the purpose of being tested, when a Miss M'George, an attendant at the Everton toffee stall, stepped forward and put her hand on the top of the lamp. Immediately she received a severe electric shock, and could not remove her hand. Another Exhibition attendant, hearing her screams, ran forward and took hold of the unfortunate young woman, but she, too, merely by taking hold of Miss M'George, received a shock which caused her to scream out. She, however, succeeded in dragging the former from her position. Both were taken to the Ambulance Hospital. Miss Woolland, the second victim by the mishap, quickly recovered, but Miss M'George seemed to have suffered severely by the shock, and was a considerable time in recovering sufficiently to leave the hospital." While we are sorry for Miss M'George's sufferings, it cannot be denied that an incident of this kind is not altogether without its value, if only in demonstrating that an electric shock is not necessarily fatal. But we should like to know what the man who lowered the lamp was doing to allow it to be meddled with in this way.

SEVERE THUNDERSTORM IN PARIS.—The following is the *Daily News* account of a severe storm in Paris on Sunday last:—"An extremely violent thunderstorm interrupted yesterday the drought in this part of the world. The weather for a few hours before it broke was suffocating in its sultriness, and the sky was so black that day was as night. Then suddenly, at two o'clock in the afternoon, a deluge of rain came pouring down, and sweeping along the streets, which in a few moments were as rivers. If all the artillery of the German Empire had been playing upon the city the noise could not, perhaps, have been greater than that caused by the fast-recurring peals of thunder. In the Avenue de Main the lightning split an elm, and stunned eight persons who were taking shelter in a shed near it.

Digitized by Google

In many parts of Paris trees have thus been damaged. A lightning rod next door to the Bank of France was struck with such force that all the panes in the glazed roof of the central court in that building were broken. A panic reigned for some moments, as it was feared that the iron roof was coming down with the glass. The office of the *Figaro* was struck by the lightning, attracted by a metal chimney pot, from which it ran to a balcony railing, and thence into the machine room where the printers were at work. It destroyed some insignificant objects, and made its exit by the shaft of a lift into a cellar."

GLASGOW.—*Industries* gives the following account of the recent negotiations for the lighting of the City Hall, Bazaar, and Municipal Buildings at Glasgow:—Some time ago the Town Council advertised for tenders for an installation of electric light for these three buildings. Two of them are close together, and the third is at a distance of a few hundred yards. The original intention was to light all three from a central station, to be situated in or near the Bazaar or public market. Between twenty and thirty tenders were received, and these differed so widely, both as to methods and costs, that the committee in whose hands the matter rested sought the advice of Mr. W. A. Bryson, electrician at the Manchester Exhibition. Mr. Bryson reported that the City Hall should be lighted by 13 to 15 arc lamps in series, and that the Bazaar should be lighted by a similar number, the current for each circuit being obtained from a dynamo and small engine under or near the Bazaar. Mr. Bryson recommended also that the Municipal Buildings should be lighted mainly by arc lamps, and the smaller rooms and corridors alone fitted with incandescent lamps, the generating plant being placed at the Bazaar or some other building within a reasonable distance of the Municipal Buildings. The committee resolved to carry out the lighting of the Municipal Buildings independently of the City Hall and Bazaar, but ultimately decided to reconsider the whole subject. One of the buildings is now approaching a stage when it will be necessary to decide promptly whether it is to be lighted by gas or electricity.

ARC LIGHTING CONTRACTS IN THE UNITED STATES.—The following figures will serve to show the average cost of electric lighting in American towns. The candle-power contracted for per lamp is invariably 2,000, except in Brooklyn, where it is only 1,200:—

Town.	No. of lamps.	Price per night. Cents.	System.	Length of contract.
New York ..	711	70	Brush United States	1 year
Philadelphia ...	525	54	Brush United States Thomson-Houston	1 year
Brooklyn	995	50	Thomson-Houston	1 year
Boston	504	65	Brush, Weston Thomson-Houston	3 years
Newark	150	50	United States Weston	3 years
Providence, R.I.	175	50	Weston Thomson-Houston	1 year
Albany	481	50	Brush	5 years
Rochester, N.Y.	309	45	Brush	5 years
	77	30		

At Albany, Boston, and Philadelphia the lamps, posts, poles, and lanterns are in part, or altogether, the property of the towns. From a note in another column it will be seen that the high price now obtained in New York has attracted competition, and the Brush and United States Companies, which now share the field between them, are likely to find a powerful rival in the Thomson-Houston.

A REMARKABLE INSTALLATION AT BRUSSELS.—The electric lighting of the Théâtre de la Monnaie at Brussels has been placed in the hands of Gérard and Co., who, we are informed, intend to employ transformers, which will be supplied with current from a generating station situated at the gas works nearly three miles distant. The installation will consist of about 400 lamps, and the contract amounts to £4,950. The transformers to be employed are of a new type, designed by M. Gérard, and provision is also made for charging a set of batteries to be capable of lighting the theatre for five hours in the case of a breakdown. Some mystery is being maintained as to the means which are to be employed for charging these batteries. It would of course be possible by means of a small alternating current machine used as a motor to commutate the transformer current and charge the cells in this way, and several experiments have recently been made in this country in the direction indicated, but the difficulty of making the motor self-starting, of exciting its field, and of suppressing sparks at the commutator has hitherto hindered any satisfactory results. In the Brussels case, however, the two first-named difficulties would be less serious because the conditions probably admit of the provision of skilled attendance in charge of the batteries. The sparking difficulty can also, we believe, be overcome. There remains the economical objection of the double transformation, but if the efficiency of the Gérard transformers is as high as is usually claimed for this class of apparatus, this objection also is not very serious. It was intended at first to employ the Gadot accumulator, but at the last moment these were abandoned in favour of the Julien. Engines are provided for 75 horse-power. The dynamos are four in number. The work is to be completed under a heavy penalty by the 1st October, and the contractor guarantees to maintain the service in good order until the 1st January, 1889.

COUPLING ALTERNATING MACHINES.—It is well known that when two alternating current machines are coupled in parallel they tend automatically to acquire uniform phase. In practice, however, if it is required to add another machine in parallel with one already at work upon a lighting circuit it is inconvenient to await this automatic adjustment, for so long as the phases are not absolutely coincident, the mean difference of potential at the lamp terminals will obviously be less than the normal. In order to overcome this difficulty Messrs. Siemens and Halske have devised an arrangement in which the machine to be brought into circuit has its terminals connected with mercury contacts which are operated by an electromagnet switch. The magnet is wound with two equal coils, one of which is placed in circuit with the latter machine and the other as a shunt with the machine already in action. The armature is held back by an opposing spring until the attraction of the core is at a maximum, which is not until the two currents are uniform in phase. The armature then falls over, bridging the mercury contacts and putting the second machine upon the lamp circuit. If Messrs. Siemens have found this arrangement to work satisfactorily in practice, we have naturally no theoretical objection to raise against it. But, taking the description as it stands, it is clear that the device is open to question, on the ground that the phase of the current in the magnet coil which is placed as a shunt upon the terminals of the machine in action is not identical with the phase in the main circuit, unless the ratio of self-induction to resistance is the same in these two branches. No doubt this difficulty might be overcome by making the resistance and self-induction of the magnet coil as small as possible, and increasing the total resistance of the shunt by the use of non-inductive resistance, such as incandescent lamps. This would probably

Digitized by Google

entail the employment of a second electro-magnetic switch, the first being used merely as a relay. The problem is a pretty one, and it obviously admits of more than one solution.

NON-POLAR DYNAMOS.—It is not our intention at the present moment to express any editorial opinion upon the merits of the controversy upon the so-called non-polar type of dynamo machine which has lately occupied our correspondence columns; but as some of our correspondents appear to be rather in want of experimental data upon which to base their theories, we print herewith the passage in De la Rive's "Electricity," to which Mr. Voice referred, somewhat inaccurately, in his first letter. De la Rive (Vol. I., page 435) says:—"Mr. Weber's experiment differs from those of Faraday in that the magnet, being arranged so as to rotate on its horizontal axis, carries a metal disc through which it passes tightly, and which can be slipped so as to be placed upon different sections of the magnet. This disc is plunged by its lower part in a cup full of mercury, into which is inserted one of the ends of the galvanometer wire, whilst the other communicates with the axis of the magnet itself. On making the magnet rotate upon its axis, a continuous current is obtained, the direction of which depends upon that of the rotation, and the intensity of which varies proportionately with the velocity of this rotation. But the intensity depends also essentially upon the power of the magnet, and especially upon the distribution assumed by the magnetism in it, for it greatly changes according as the magnet that serves for the operation is subjected or not at its two extremities to the action of the contrary poles of two powerful auxiliary magnets that are brought near to it. The length of the space on the surface of the magnet and parallel to its axis has no sensible influence over the force of the current. For this force is the same when the brass disc being fixed at one or other of the two extremities of the magnet, the end of the galvanometer not in communication with the disc is placed in contact with the north end and the south end—that is to say, with that which is nearest to or with that which is most distant from the disc. However, the absolute effect is less considerable in this case that it is when the brass disc is in the middle of the magnet."

PHELPS'S ELECTRO-MOTOR ROCK DRILL.—Now that the construction of electric motors has at length been placed upon a sound footing, both in this country and in America, the application of electricity to the working of machinery and machine tools may be expected to receive a rapid development. One of the most obvious applications of this nature is for driving rock drills. This was first attempted some years ago by Messrs. Siemens and Halske, but at that period the weight and efficiency of the then available motors was against the complete success of the method. More recently, as our readers are aware, Mr. C. E. Rowan has worked in the same direction, and has attained very promising results in drilling and riveting iron plates in the shipbuilding yards at Dumbarton. We now learn that Mr. Phelps (whose name is already known in connection with induction telegraphs applied to moving trains) has designed a rock drill applicable for mining and tunnelling operations. As regards economy machines of this class ought now to be able to beat compressed air entirely out of the market were it not for the fact that ventilation is provided at the same time by the air motors. When, however, we remember that the efficiency of the latter apparatus seldom exceeds 25 per cent., there is room to hope that the margin of economy in the use of electricity may permit the employment of separate ventilating appliances, in which also electricity may play a useful part. It is to us a matter of some surprise that so few electrical firms have as yet broken ground in this and many similar directions. In the Phelps rock drill the drill itself is driven by two short cranks attached to either side of the armature; but in order to give a thrusting rather than a hammer action, and at the same time to deaden the shock and jar upon the frame, two spiral springs are attached to the stock of the axle in such a manner that in an extreme position one spring is compressed and the other extended. The remaining mechanical details appear to have been well thought out, but the motor, which has been especially designed to meet the above conditions, will scarcely commend itself to the English eye. The armature is of the Gramme ring type, and is mounted between the poles of two horseshoe magnets. The four poles are not only unsymmetrical, but they are flat at the ends, and project considerably beyond the armature at either side.

MAKING MIRRORS FOR REFLECTING GALVANOMETERS.—Dr. James B. Williams, writing in the *Electrical World*, of New York, gives the following directions to amateurs who wish to make their own mirrors for reflecting galvanometers:—"The making of these little mirrors is a tedious operation to many, but a method practised by myself, and which has given very good results, is the following: Take five or six thin glass circles, such as are used in mounting microscopic objects, and clean them thoroughly by rubbing them with a small piece of cotton tied to a stick, which has been dipped in nitric acid. Then wash them in a solution of caustic potash, or strong ammonia water, and finally rinse them first in clean and then in distilled water. Dry them thoroughly with a piece of soft linen rag, and fasten them on a piece of cardboard with mucilage, by placing small drops of mucilage near the edge of a card and allowing the circles to fall upon them. Next, take a piece of good looking glass and cut out circles of the alloy upon the back of it near the edge, by laying a coin a little larger than the glass circles upon the alloy, and draw a sharp pointed instrument around the edge of the coin. Remove all of the alloy between the circles and the edge of the looking glass so that the circles of alloy can be slid over the surface of the looking glass and on to the thin glass circles gummed on the card. The circles of alloy are loosened from the looking glass by placing a globule of mercury upon them and spreading it over them with the finger; after which they can be gently pushed on to the glass circles, the edge of the card being held against the edge of the looking glass. After placing the circles of alloy upon the thin glasses, press them gently with the fingers upon all portions. Next cut discs from a piece of heavy tinfoil, a little larger than the circles of alloy, lay them gently upon the latter, and press them firmly upon the alloy. By so doing all of the superfluous mercury is removed from the alloy and unites with the tinfoil. The outer alloy, formed by the union of the mercury and tinfoil, is then removed by scraping it gently with the edge of a sharp knife blade. A coating of shellac dissolved in alcohol is then painted over the backs of the mirrors, and after it has become dry the mirrors are removed from the card by moistening the latter with water. I have used mirrors made according to the above-described process in my galvanometers and electrometer, and find they will, when used with a biconvex lens, give an excellent definition of a cross hair three and four feet away from the mirror. The beginner had better practice upon thick glass circles, for he will be most certain to break thin ones while pressing the alloy upon the glasses. The mirrors will be found to answer all purposes except in the cases where an extremely light mirror (as in a Thomson astatic galvanometer of high resistance) is required, when the silvering process should be used. If the process be successfully performed, the mirrors can be broken before the alloy will leave the glass."

COMPARISON BETWEEN THE VIEWS OF DR. ARRHENIUS AND PROF. ARMSTRONG ON ELECTROLYSIS.

BY OLIVER LODGE, F.R.S.

A Communication to be made to the British Association Committee on Electrolysis.

It may be convenient to summarise the main views of Prof. Armstrong concerning electrolytic conduction, as expressed in his Royal Society Memoir (*Proc.* Royal Society, No. 243, 1886). He discards the view of exact equivalence between the positive and negative atoms of a compound, considering that no ordinary molecule is really saturated, but that its electro-negative element has an unsatisfied or residual affinity, with which it is ready to cling on to fresh atoms or to other like molecules. By means of these residual affinities of unsatisfied atoms he imagines molecular aggregates to be built up. And he considers a concentrated substance in the liquid state to be largely or wholly composed of these complex molecular aggregates, each in a nearly or quite saturated, and therefore inert, condition. The effect of dilution, however, is to break up these aggregates into simpler molecules, until, in an extremely dilute solution, the molecules may be as separated and as simple as they are in the gaseous state.

So far the views of Arrhenius* somewhat correspond. Without any doctrine of residual affinity as accounting for them Arrhenius also postulates the existence of molecular aggregates, which he imagines to be broken up by dilution; but he goes further, and imagines a certain number of the molecules themselves broken up by dilution into their constituent atoms, *i.e.*, he postulates real dissociation after the manner of Williamson and Clausius, a hypothesis for which Prof. Armstrong sees no necessity, and to which he apparently perceives some chemical objection.

The dissociated molecules are called by Arrhenius the "active part" of the liquid, and are believed to be the only ones which take part directly either in chemical action or in electrolytic condition. These are the molecules which are constantly exchanging their atoms, either with each other or with foreign molecules, and so giving rise to double-decomposition and ordinary chemical action. All other molecules, having their atoms firmly combined, are inert. Heating and dilution increases the active portion, *i.e.*, the proportion of dissociated molecules, and thus intensifies at the same time the chemical power and the electrolytic conductivity of the compound. To every state of temperature or admixture, a certain proportion exists between the active and inactive molecules of a given substance; and thus its "activity" or "avidity" in chemical reaction, as well as the current it can convey under the influence of a given E.M.F., *i.e.*, its conductivity, is regulated and determined. The velocity of chemical action between the mixed substances, *i.e.* the rate at which their molecules interchange atoms, can thus be calculated in arbitrary time-units from a knowledge of the conductivity of the constituent substances; and the final state of equilibrium is obtained by putting this rate equal to zero.

The special point of Arrhenius's paper is therefore not any peculiar view which he holds regarding the nature of electrolysis, for his view is a perfectly orthodox one, but it is the application which he makes of it in the consideration of all manner of chemical reactions; he attempts, in fact, an Electrolytic Theory of Chemistry.

Prof. Armstrong, on the other hand, holds, provisionally at any rate, quite heterodox views as to the nature of electrolysis, which, so far as I understand them, appear to be these:—

So soon as an E.M.F. is applied to a liquid a locomotion of the *molecules* past each other begins, as evidenced by the known occurrence of electric endosmose. By this process every salt molecule is brought within range of a water molecule as they slide past each other, and the residual affinity of some constituent of each of two molecules straining at each other under these conditions, superadded to the strain already set up by the applied E.M.F., is sufficient to effect disruption of the molecule, whose separated atoms then travel opposite ways to the electrodes, carrying their charges with them, and conduction occurs in the manner ordinarily assumed. For instance, in a solution of HCl in H_2O, the O is straining at the Cl, and this force, as they flow past each other, is sufficient to assist the applied E.M.F. to produce disruption and interchange, *i.e.*, to bring about the same result on the Williamson-Clausius dissociated condition ordinarily supposed to exist *before* the action of E.M.F.

If, however, the molecules in the liquid are all complex molecules, or aggregate of a large number of atoms, hanging together by the residual affinity of each, these residual affinities are in the complex so nearly satisfied that they have no further power to act on a water or other molecule; and they thus resist being broken up, and refuse to conduct a current. A liquid composed wholly of such complex aggregates is thus not an electrolyte; and Armstrong calls it a pseudo-dielectric.

A liquid which contains among a large proportion of such aggregates a few simple molecules here and there is an electrolyte but a very badly conducting one. Its conductivity increases as the aggregates get broken down, whether by heat or by dilution.

It will be observed that this hypothesis does not dispense with dissociation; it only denies dissociation previous to the application of E.M.F. So soon as E.M.F. is applied, mutual action between the molecules, assisting the strain caused by the E.M.F. itself, produces the very state of dissociation postulated by all physicists as necessary for actual electrolytic conduction.

Neither does the hypothesis dispense with a dissociating power of the solvent; it only limits its power to the breaking down of complex molecules, instead of allowing it to break up the simple molecules themselves. It is not supposed able to do this latter until aided by applied E.M.F.

To summarise.—The orthodox view supposes fully combined molecules, whether aggregates or not, to be undecomposable by any moderate E.M.F.; but it supposes a certain proportion of them split up or dissociated, either actually or potentially, by addition of a foreign body. Not necessarily a *solvent*: it pictures the dissociation of water by salt quite as easily as that of salt by water. Each atom while in the nascent or uncombined state has associated with it a definite electric charge, and these loose electrified atoms are thus immediately amenable to the smallest directive E.M.F.

Armstrong's view supposes complex molecules to be undecomposable by any moderate E.M.F., but it imagines a certain proportion of them split up or decomposed into simpler molecules by the action of a solvent. It supposes, further, a tendency or endeavour on the part of the water to split up these simple molecules still more into their constituent atoms; but it asserts that the water is unable to effect this until aided both by an extra strain, in the shape of an externally applied E.M.F., and by the locomotive disturbance or endosmose thereby set up in the liquid.

A third view there is, which must probably have been held more or less distinctly by several physicists, and which for several reasons usually commends itself to me, viz., that all *simple* molecules are strongly combined, and therefore intractable to feeble E.M.F.'s; and that most perfectly pure bodies, undisturbed by heat or by admixture with foreign matter, have their molecules in this condition. When, however, two or more substances (like salt and water for instance) are mixed together, their simple molecules combine into somewhat indefinite molecular aggregates or hydrates of complex structure, in which it may happen either that some of the outlying atoms are not held with full vigour, and so become partially free and able to interchange with other similarly placed atoms, or else that by the collision of the unwieldy aggregates with each other the atoms of one molecule are brought so close to the respectively opposite atoms of another molecule that a mutual interchange occurs.

For it is well known that it is quite unnecessary to postulate atoms as hovering around in an entirely free or disemmoleculed condition. All that is wanted to explain the facts of electrolysis

* "Recherches sur la Conductibilité galvanique des Electrolytes (152 pages), par Svanté Arrhenius. Mém. presenté à l'Acad. des Sciences de Suède le 6 Juin, 1883. Abstract and semi-translation appear in recent B.A. Report.

Digitized by Google

is a certain number of atomic interchanges occurring at random; for the slightest E.M.F. will then suffice to exert a directive influence one way or the other on the atoms during their infinitesimal moment of freedom.

The operation is perhaps more simple to contemplate if the atoms are imagined to be actually, instead of only, so to speak, potentially free; but the result is the same, and, of course, the conductivity will depend upon the number of such "free" atoms existing in the solution, the *molecular* conductivity km representing the proportion of such free atoms to the whole. It is upon this very same proportion, according to Arrhenius, that the chemical activity of the substance depends.

Whatever be the most satisfactory form of hypothesis to hold at present, I am bound to say that the hypothesis of Dr. Armstrong does not commend itself to me. And that for several reasons.

I make no objection to his notion of residual affinity, nor to the formation of molecular aggregates by means of it. These are points for the consideration of chemists. The objectionable, and I venture to think fatal, part of his hypothesis, is where he supposes dissociation to be produced by means of the applied E.M.F., instead of independently of it. Few things are more certain than this, that an electrolyte is incompetent to resist the smallest E.M.F. really applied to it (*i.e.*, not applied only to electrodes.) If the molecules have to be torn asunder by any action depending on the magnitude of the applied E.M.F., it must be possible to choose an E.M.F. too weak to effect decomposition. A substance which needs an E.M.F. to tear its molecules asunder in the interior of its mass is *ipso facto* a dielectric—it may be a very weak one—but it is not an electrolyte. All that a slope of potential can possibly achieve in the interior of an electrolyte is to direct the procession of otherwise randomly moving atoms. This is of course the foundation of the theory of Williamson and Clausius; and all experimental knowledge acquired since the time it was first promulgated with regard to the obedience of electrolytes to Ohm's law, down to the researches of Prof. Fitzgerald and Mr. Trouton, communicated in part to the last British Association and still going on, tends but to confirm and strengthen that position.

Of course, at surfaces of discontinuity, *i.e.*, at electrodes, electrolytes need a finite E.M.F. to liberate their ions, but the range over which the stress here concerned acts is of atomic dimensions, say 10^{-8} centimetre from each electrode. There is no such finite stress needed, or possible, in the interior of a homogeneous liquid.

A minor objection to Dr. Armstrong's hypothesis may be made at the point where he supposes *endosmose* to precede conduction, and to be a phenomenon independent of surface contact. It is not easy, again, to imagine why his molecules should be travelling past *each other* in the fluid, nor why, even if they did, this fact should assist their previously incompetent forces to disrupt each other.

Unless every molecule is supposed to be in a condition extremely like every other molecule, which is quite contrary to the usual doctrine of averages as applied to molecules, it is difficult to believe that a number of molecules are in such a state of strain as to be made to break up with mere gentle locomotion, and yet that none of them shall be able to break up without such assistance.

I trust that in thus criticising Prof. Armstrong's views it will be perceived that I am actuated by none but friendly motives, and that I fully recognise the importance of the effort he is making to think out chemical phenomena in a physical way, and generally to associate Chemists and Physicists more closely together.

INCANDESCENT LAMP MANUFACTURE.—XXI.

BY J. SWINBURNE.

Testing (continued).

Before discussing the photometry of incandescent lamps it will be necessary to explain what is meant by such terms as "efficiency," "light of so many candles," &c., as these terms are generally used somewhat loosely.

If the electromotive force of a lamp is gradually increased from 0 till the lamp breaks, the light of the lamp increases, and so does the electrical power absorbed by the lamp. The light increases more quickly than the power, so that the ratio of the light to the power used increases.

If a body is at a white heat, so as to emit light, it emits light in all directions. The total light emitted is generally called the spherical intensity, but will here be called the total emission. When the light from a square centimetre of melting platinum is taken as the unit of white light the total emission is not referred to, and only the light emitted in a direction at right angles to the surface of the melting platinum is taken into account. If the surface of the melting platinum were turned through an angle so that the line from it to the observer was no longer normal to the surface, the light emitted in this direction would decrease. If the observer is so far off that a centimetre is very small in comparison with the distance, the light observed is equal to the light observed when the plane of the surface was at right angles, multiplied by the cosine of the angle the surface is turned through. Thus when the platinum is turned through 90 deg., it is edge on towards him and emits no light in his direction. The light emitted in his direction thus varies as the projection of the surface on a plane at right angles to the line from the observer. The light emitted in the direction of the observer thus varies as the apparent area of the source of light, or as the area of paper it would occupy if the observer made a perspective drawing of it as he saw it.

Any illuminating surface may be looked upon as made up of an infinite number of infinitesimally small planes. Suppose a line drawn from the centre of one of these planes, dS, to the observer; the light emitted would be proportional to the intensity of the source—that is, to the amount of light which would be emitted by a plane square centimetre of the surface in a direction at right angles to it; call this I; to the area dS, and the cosine of the angle, which we may call ϵ, which the normal to the plane makes with the line from the little plane to the observer. The amount of light which enters the eye of the observer varies inversely as the square of the distance r from the plane, so that the light observed from the little plane is $\frac{1}{r^2}$ I cos ϵ dS, and the whole light which enters the eye of the observer is $\iint \frac{1}{r^2}$ I cos ϵ dS, an expression which will be familiar to electrical readers. This means that the light received at any point from a source of any shape whose surface is uniformly luminous varies as the solid angle subtended by the surface at the point. Thus to find the intensity of illumination at a point on the disc of the photometer due to any source of light, such as, for instance, a lump of white hot carbon, imagine a sphere of one centimetre radius described round the point, and imagine a wire with one end fastened at the point on the disc, stretched past the lump of carbon, and held so as to touch the carbon. If the wire was moved so as to go round the lump of carbon just touching it and still stretched, it would trace out an irregular pyramid, with the apex at the point on the disc; this would be the solid angle. The wire would also trace out an irregular surface on the sphere, which would be the shape of the carbon lump as seen by a tiny observer at the point on the screen. The area of this surface would be a measure of the solid angle, and if multiplied by the intensity of unit surface of the lump would be a measure of the intensity of the illumination at the point on the disc. This explains why such a thing as a white hot lamp carbon looks equally bright all over, so that it is impossible to see with one eye whether it is round or flat. It also shows why a rough surface and a smooth give out the same light in any direction if the outlines are the same; thus, if two carbons are the same size and are run at the same temperature they give the same light, even if one is rough and the other smooth.

Instead of talking about the light received by the observer's eye the term illumination may be used, the illumination at any point is then the light received per square centimetre of surface.

The next point to consider is the relation between the light

COMPARISON BETWEEN THE VIEWS OF DR. ARRHENIUS AND PROF. ARMSTRONG ON ELECTROLYSIS.

BY OLIVER LODGE, F.R.S.

A Communication to be made to the British Association Committee on Electrolysis.

It may be convenient to summarise the main views of Prof. Armstrong concerning electrolytic conduction, as expressed in his Royal Society Memoir (*Proc.* Royal Society, No. 243, 1886). He discards the view of exact equivalence between the positive and negative atoms of a compound, considering that no ordinary molecule is really saturated, but that its electro-negative element has an unsatisfied or residual affinity, with which it is ready to cling on to fresh atoms or to other like molecules. By means of these residual affinities of unsatisfied atoms he imagines molecular aggregates to be built up. And he considers a concentrated substance in the liquid state to be largely or wholly composed of these complex molecular aggregates, each in a nearly or quite saturated, and therefore inert, condition. The effect of dilution, however, is to break up these aggregates into simpler molecules, until, in an extremely dilute solution, the molecules may be as separated and as simple as they are in the gaseous state.

So far the views of Arrhenius* somewhat correspond. Without any doctrine of residual affinity as accounting for them Arrhenius also postulates the existence of molecular aggregates, which he imagines to be broken up by dilution; but he goes further, and imagines a certain number of the molecules themselves broken up by dilution into their constituent atoms, *i.e.*, he postulates real dissociation after the manner of Williamson and Clausius, a hypothesis for which Prof. Armstrong sees no necessity, and to which he apparently perceives some chemical objection.

The dissociated molecules are called by Arrhenius the "active part" of the liquid, and are believed to be the only ones which take part directly either in chemical action or in electrolytic condition. These are the molecules which are constantly exchanging their atoms, either with each other or with foreign molecules, and so giving rise to double-decomposition and ordinary chemical action. All other molecules, having their atoms firmly combined, are inert. Heating and dilution increases the active portion, *i.e.*, the proportion of dissociated molecules, and thus intensifies at the same time the chemical power and the electrolytic conductivity of the compound. To every state of temperature or admixture, a certain proportion exists between the active and inactive molecules of a given substance; and thus its "activity" or "avidlty" in chemical reaction, as well as the current it can convey under the influence of a given E.M.F., *i.e.*, its conductivity, is regulated and determined. The velocity of chemical action between the mixed substances, *i.e.* the rate at which their molecules interchange atoms, can thus be calculated in arbitrary time-units from a knowledge of the conductivity of the constituent substances; and the final state of equilibrium is obtained by putting this rate equal to zero.

The special point of Arrhenius's paper is therefore not any peculiar view which he holds regarding the nature of electrolysis, for his view is a perfectly orthodox one, but it is the application which he makes of it in the consideration of all manner of chemical reactions; he attempts, in fact, an Electrolytic Theory of Chemistry.

Prof. Armstrong, on the other hand, holds, provisionally at any rate, quite heterodox views as to the nature of electrolysis, which, so far as I understand them, appear to be these:—

So soon as an E.M.F. is applied to a liquid a locomotion of the *molecules* past each other begins, as evidenced by the known occurrence of electric endosmose. By this process every salt molecule is brought within range of a water molecule as they slide past each other, and the residual affinity of some constituent of each of two molecules straining at each other under these conditions, superadded to the strain already set up by the applied E.M.F., is sufficient to effect disruption of the molecule, whose separated atoms then travel opposite ways to the electrodes, carrying their charges with them, and conduction occurs in the manner ordinarily assumed. For instance, in a solution of HCl in H_2O, the O is straining at the Cl, and this force, as they flow past each other, is sufficient to assist the applied E.M.F. to produce disruption and interchange, *i.e.*, to bring about the same result on the Williamson-Clausius dissociated condition ordinarily supposed to exist *before* the action of E.M.F.

If, however, the molecules in the liquid are all complex molecules, or aggregate of a large number of atoms, hanging together by the residual affinity of each, these residual affinities are in the complex so nearly satisfied that they have no further power to act on a water or other molecule; and they thus resist being broken up, and refuse to conduct a current. A liquid composed wholly of such complex aggregates is thus not an electrolyte; and Armstrong calls it a pseudo-dielectric.

A liquid which contains among a large proportion of such aggregates a few simple molecules here and there is an electrolyte but a very badly conducting one. Its conductivity increases as the aggregates get broken down, whether by heat or by dilution.

It will be observed that this hypothesis does not dispense with dissociation; it only denies dissociation previous to the application of E.M.F. So soon as E.M.F. is applied, mutual action between the molecules, assisting the strain caused by the E.M.F. itself, produces the very state of dissociation postulated by all physicists as necessary for actual electrolytic conduction.

Neither does the hypothesis dispense with a dissociating power of the solvent; it only limits its power to the breaking down of complex molecules, instead of allowing it to break up the simple molecules themselves. It is not supposed able to do this latter until aided by applied E.M.F.

To summarise.—The orthodox view supposes fully combined molecules, whether aggregates or not, to be undecomposable by any moderate E M.F.; but it supposes a certain proportion of them split up or dissociated, either actually or potentially, by addition of a foreign body. Not necessarily a *solvent:* it pictures the dissociation of water by salt quite as easily as that of salt by water. Each atom while in the nascent or uncombined state has associated with it a definite electric charge, and these loose electrified atoms are thus immediately amenable to the smallest directive E.M.F.

Armstrong's view supposes complex molecules to be undecomposable by any moderate E.M.F., but it imagines a certain proportion of them split up or decomposed into simpler molecules by the action of a solvent. It supposes, further, a tendency or endeavour on the part of the water to split up these simple molecules still more into their constituent atoms; but it asserts that the water is unable to effect this until aided both by an extra strain, in the shape of an externally applied E.M.F., and by the locomotive disturbance or endosmose thereby set up in the liquid.

A third view there is, which must probably have been held more or less distinctly by several physicists, and which for several reasons usually commends itself to me, viz., that all *simple* molecules are strongly combined, and therefore intractable to feeble E.M.F.'s; and that most perfectly pure bodies, undisturbed by heat or by admixture with foreign matter, have their molecules in this condition. When, however, two or more substances (like salt and water for instance) are mixed together, their simple molecules combine into somewhat indefinite molecular aggregates or hydrates of complex structure, in which it may happen either that some of the outlying atoms are not held with full vigour, and so become partially free and able to interchange with other similarly placed atoms, or else that by the collision of the unwieldy aggregates with each other the atoms of one molecule are brought so close to the respectively opposite atoms of another molecule that a mutual interchange occurs.

For it is well known that it is quite unnecessary to postulate atoms as hovering around in an entirely free or disemmoleculed condition. All that is wanted to explain the facts of electrolysis

INCANDESCENT LAMP MANUFACTURE.—XXI.

BY J. SWINBURNE.

Testing (continued).

Before discussing the photometry of incandescent lamps it will be necessary to explain what is meant by such terms as "efficiency," "light of so many candles," &c., as these terms are generally used somewhat loosely.

If the electromotive force of a lamp is gradually increased from 0 till the lamp breaks, the light of the lamp increases, and so does the electrical power absorbed by the lamp. The light increases more quickly than the power, so that the ratio of the light to the power used increases.

If a body is at a white heat, so as to emit light, it emits light in all directions. The total light emitted is generally called the spherical intensity, but will here be called the total emission. When the light from a square centimetre of melting platinum is taken as the unit of white light the total emission is not referred to, and only the light emitted in a direction at right angles to the surface of the melting platinum is taken into account. If the surface of the melting platinum were turned through an angle so that the line from it to the observer was no longer normal to the surface, the light emitted in this direction would decrease. If the observer is so far off that a centimetre is very small in comparison with the distance, the light observed is equal to the light observed when the plane of the surface was at right angles, multiplied by the cosine of the angle the surface is turned through. Thus when the platinum is turned through 90 deg., it is edge on towards him and emits no light in his direction. The light emitted in his direction thus varies as the projection of the surface on a plane at right angles to the line from the observer. The light emitted in the direction of the observer thus varies as the apparent area of the source of light, or as the area of paper it would occupy if the observer made a perspective drawing of it as he saw it.

Any illuminating surface may be looked upon as made up of an infinite number of infinitesimally small planes. Suppose a line drawn from the centre of one of these planes, dS, to the observer; the light emitted would be proportional to the intensity of the source—that is, to the amount of light which would be emitted by a plane square centimetre of the surface in a direction at right angles to it; call this I; to the area dS, and the cosine of the angle, which we may call ϵ, which the normal to the plane makes with the line from the little plane to the observer. The amount of light which enters the eye of the observer varies inversely as the square of the distance r from the plane, so that the light observed from the little plane is $\frac{1}{r^2} I \cos \epsilon \, dS$, and the whole light which enters the eye of the observer is $\iint \frac{1}{r^2} I \cos \epsilon \, dS$, an expression which will be familiar to electrical readers. This means that the light received at any point from a source of any shape whose surface is uniformly luminous varies as the solid angle subtended by the surface at the point. Thus to find the intensity of illumination at a point on the disc of the photometer due to any source of light, such as, for instance, a lump of white hot carbon, imagine a sphere of one centimetre radius described round the point, and imagine a wire with one end fastened at the point on the disc, stretched past the lump of carbon, and held so as to touch the carbon. If the wire was moved so as to go round the lump of carbon just touching it and still stretched, it would trace out an irregular pyramid, with the apex at the point on the disc; this would be the solid angle. The wire would also trace out an irregular surface on the sphere, which would be the shape of the carbon lump as seen by a tiny observer at the point on the screen. The area of this surface would be a measure of the solid angle, and if multiplied by the intensity of unit surface of the lump would be a measure of the intensity of the illumination at the point on the disc. This explains why such a thing as a white hot lamp carbon looks equally bright all over, so that it is impossible to see with one eye whether it is round or flat. It also shows why a rough surface and a smooth give out the same light in any direction if the outlines are the same; thus, if two carbons are the same size and are run at the same temperature they give the same light, even if one is rough and the other smooth.

Instead of talking about the light received by the observer's eye the term illumination may be used, the illumination at any point is then the light received per square centimetre of surface.

The next point to consider is the relation between the light

Digitized by Google

and the temperature of the carbon. Early in the century Draper made some rough experiments by which he showed that at the same temperature all bodies give out light of the same colour. This subject has since been followed up by many others, notably by Provostaye, Desains, and Kirchhoff. This law is very important in connection with incandescent lamps, for it shows that it is impossible to find a carbon which will at any temperature give out a larger proportion of the energy supplied it as light than another carbon does at the same temperature. That is to say, given the same vacuum, efficiency is a matter of temperature only, and one kind of carbon cannot give a higher efficiency than another without being run at a higher temperature. The only way, therefore, to get a carbon to give more light per watt is to make it so that it will stand a higher temperature without breaking.

Different bodies have different emissivities—that is to say, a piece of one with a total surface of one centimetre will at a given temperature give off more light than another piece of the same size at the same temperature. It will also give off more heat. If the temperatures are kept the same the first will need more power to keep the temperature up; but the light will be of the same colour in both cases, differing in quantity only. The efficiency will be the same, as the light will be of the same colour—that is to say, the same proportions of light and heat of different vibration frequencies will be emitted, so that the candles per watt will be the same.

These points have been dwelt on at some length because there are a great many popular errors on these subjects. Every now and then a maker brings out a carbon which he supposes has a higher efficiency than other makers' carbons. Efficiency is merely a matter of the temperature of the carbon if the vacuum is the same in each case, so that it is nonsense to say that lamps of one maker have a higher efficiency than those of another. All properly exhausted lamps have the same efficiency when seen at the same temperature—that is to say, at the same colour. One maker's lamp may stand being run brighter than another maker's without breaking, and is then a better lamp; but it cannot give a higher efficiency without being run brighter. If a lamp has a bad vacuum, of course heat will be conducted away by convection, and it will then take more power to keep the carbon at a given temperature, and so the efficiency will be comparatively low if the lamp is run at the same temperature as another lamp, and if the power is increased so that the lamp runs at the same efficiency it will have to be run at a higher temperature to make up for the loss by convection. There seems to be no difference of loss of heat by convection in most lamps by well-known English makers; but in America they do not seem to have studied exhausting so thoroughly, and so they may make what might be called low efficiency lamps.

The writer has tried experiments to see if carbons flashed at a high temperature so as to have a bright grey surface had more or less emissivity than when black. As it was difficult to measure the sizes of the carbons, a lamp was first made without flashing the carbon, and the power absorbed at ·3 candle-power watt was measured. The lamp was then opened and the carbon was flashed in highly rarefied coal gas, so that it became bright grey without getting perceptibly thicker. It was then pumped and tested again at the same efficiency, but took the same power, which shows that the emissivity was sensibly the same. If the emissivity were less it would of course have taken less power, being, say, a 15 candle-power instead of a 16 candle-power lamp, and if the same power as at first had been supplied it would have given more than 16 candle-power and would have run at a higher efficiency, but would have been at a higher temperature and would have given a whiter light.

As the melting platinum standard is not likely to come into immediate use, the light of lamps is always measured in standard candles. No one thinks of using standard candles for testing work. Generally some other standard, which has been compared with some such standard as the Gas Referees, is used. As by the "light" of a standard candle the total emission from the candle is not intended, so in the case of incandescent lamps the horizontal emission only is supposed to be measured. This would give no trouble if the horizontal emission were always the same proportion of the total emission of a lamp; but it is not, as the proportion evidently depends on the shape of the carbon. If two carbons of the same diameter and length, and therefore of the same surface, were made into lamps, the carbon in one lamp being as in the Swan lamp, and in the other in the form of a double corkscrew, as in the Wright and Mackie lamp, and if they were run at the same temperature, the carbon in the Swan lamp would obviously give more light horizontally than the other.

It becomes necessary, therefore, to define the term "candle-power" so that it depends on the size and temperature of the carbon and on nothing else, unless, indeed, it is necessary to include the emissivity, as the writer's experiments are scarcely conclusive on that point. The efficiency in candles per watt is, then, a measure of the temperature. This is of vital importance, as lamps should be run as bright as it is possible to run them without breaking them. One way would be to suppose a carbon measured as a sphere of the same surface, so that it would give out the same light in all directions; but this would be objectionable, because a lamp of the same nominal power as a gas jet would really give more light, so that the public, who would not understand that an electric lamp gave more light all round than a gas jet of the same nominal candle-power, would think gas cheaper. The writer always defines the candle-power as the light a carbon would give horizontally if it were in the form of a cylinder of the same surface held vertically. This seems much the simplest way, as in many cases it admits of direct measurement. Thus a carbon of circular section, bent into the form of a single loop, is simply held flatways towards the photometer.

If the carbon is bent into two or three loops it may be treated in the same way, as such carbons are thin, and the area covered by one part crossing in front of another is too small to make any perceptible difference. There is, of course, a small error due to the turns of the spiral not being in the same plane, so that their projection in the direction of the screen is slightly lessened—that is to say, an eye at the photometer would see these parts of the carbon what an artist would call foreshortened.

RECENT IMPROVEMENTS IN THE CARDEW VOLTMETER, PATERSON AND COOPER TYPE.

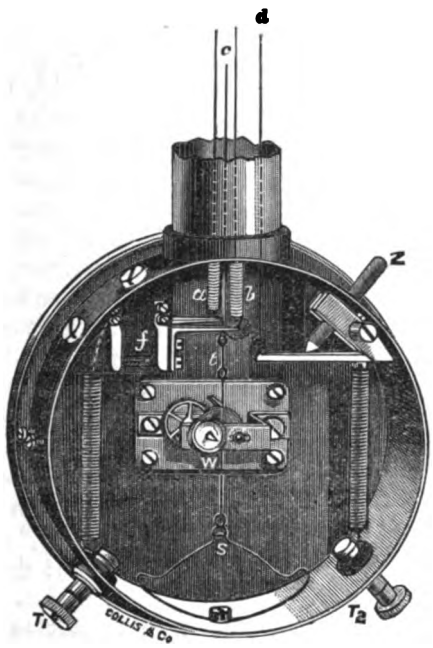
The annexed engraving shows an interior view of the latest form of the Cardew voltmeter, as constructed by Messrs. Paterson and Cooper. This instrument, as is well known, indicates difference of potential by the expansion of a fine wire heated by the passage of the current. Although this principle is sufficiently simple in theory, yet the construction of a practicable instrument required from the inventor a considerable amount of mechanical skill and ingenuity. Messrs. Paterson and Cooper have directed their endeavours towards simplifying the constructive details as much as possible. To this end they have, in the first place, done away with the supporting rods of the iron and brass by which the fine platinum-silver wires were upheld, and which were enclosed in the external brass tube. Instead of this arrangement compensation for temperature variation is secured by making the protecting tube itself in two parts properly proportioned, the lower of brass and the upper of iron. This modification enables high reading instruments to be made with four lengths of wire all in one tube, whereas previously two parallel tubes were employed to get room for the supporting rods.

The case containing the gearing of the instrument before us measures 6in. diameter by 2in. deep, the tube is 3ft. in length by 1½in. diameter, and the dial is calibrated up to 360 volts. The path of the current through the instrument is as follows:—

From the left-hand terminal T_1 a helix of silk-covered wire leads to a fuse piece, *f*, of 0·0015 platinum wire, mounted upon a block of vulcanised fibre. From thence the circuit is continued through the lower projecting arm to the German silver spiral *a*, which is about 1in. in length, and from this a length

Digitized by Google

of nearly 3ft. of ·0025 platinum-silver wire extends to the top of the tube, where it is made fast to an insulated copper bar. This is not the working wire, but is merely employed to gain resistance. Its expansion is taken up by the German silver spring. A second length of idle wire is attached at the top to the same bar, and descends to the second German silver spring *b*. This spring is secured to an insulated brass arm supported by the vulcanised fibre block. In the figure it will be seen that this arm, although lying very close to the fuse piece *f*, is not actually connected with the latter. From the lower end of the spring *b* a small platinum spiral is led off and is connected with the lower end of the working wire *c*. This wire terminates at the bottom in a loop, and to this loop is attached a short piece of silk thread, *t*, by which it is mechanically united to a separate piece of wire. The latter wire makes a turn around the pulley W, and is finally attached to the looped spring *s*, by which, together with the working wire, it is held taut. The working wire is thus insulated from the case and from the gearing.



An Improved Cardew Voltmeter.

From the end where it is fastened to the silk thread *t* and to the idle wire *b* the wire *c* extends to the top of the tube and passes over a brass pulley insulated from the case by jewels in which it is pivoted, thence the same wire (now marked *d* in the figure) descends to the brass arm seen on the right, which is connected with the terminal T_2 by a helix of silk-covered copper wire. By the way, although it is a comparatively small point, yet since the avoidance of self-induction forms the chief *raison d'être* of the instrument, it might be as well if Messrs. Paterson and Cooper avoided the use of these helices, which are somewhat unnecessarily long and compact.

In the older types the loss of zero, after the instrument has been in use for a short time, is often a source of trouble. To avoid this the bar on the right, to which the wire *d* is attached, is hinged at the back, and a stiffly set screw, Z, bearing upon this, projects outside the case and forms a very convenient mode of adjusting the needle to zero when necessary.

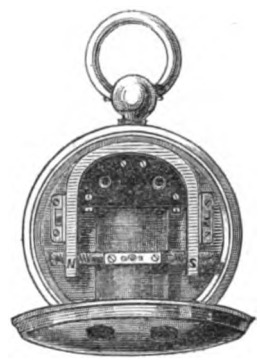
Returning to the gearing, we have seen that the wire passing round the brass pulley W is attached to the working wire by a silk thread, so that this part is entirely distinct from the electrical circuit. On the staff of the pulley is a toothed wheel, seen at the back, which gears with a small pinion upon the shaft of the pointer, and by which the extension of the wire is considerably magnified. The movement of the pointer is made against a hair spring, which keeps the pinion teeth always hard against the wheel teeth and so prevents back lash. All the *pivots* are end stone jewelled, so that the friction of the instrument is very slight.

It may be added that the object of putting the additional resistance in the form of fine stretched wire is not only to avoid self-induction, but also to obtain a more rapid cooling after being used for high E.M.F.'s.

We have only to add that the workmanship and finish of the instrument are excellent throughout.

A POCKET VOLTMETER.

The adjoining illustration represents a nickel-cased pocket voltmeter, and is drawn to a scale of one-half the actual size. The instrument is about the same dimension and shape as an old-fashioned turnip watch, and is shown in the figure with the case open at the back. It will be seen that the construction is of the Ayrton and Perry permanent magnet type. Connection is made without opening the case by pushing the wires through two small holes in the cover (these holes can be seen in the figure). The wires are then gripped by a spring catch, which secures a firm contact. On the front of the case is a glass-covered dial, upon which the pointer indicates the volts, the calibration being for direct reading. The needle is mounted upon a pivot working on jewels. The instrument from which

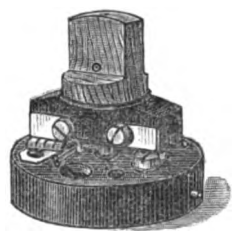


Pocket Voltmeter. (Half size.)

our illustration was drawn weighs just 6oz., and is calibrated up to 40 volts. The scale is of sufficient size to enable one volt to be read with ease, and we understand that they are made of the same dimensions, but with different winding, to read up to 120 volts. Messrs. Paterson and Cooper are the makers.

COMBINED SWITCH AND FUSE BLOCK.

The adjoining figure shows a neat and simple form of combined lamp switch and fuse block. The switch is of the bridge type,



A Combined Switch and Fuse Block.

rubbing contact being made on both sides, and pressure is secured by forming the lower contact plates of brass pieces bent twice at right angles under screws at each end. The fuse is placed between the two screws shown upon the front of the bridge. A stout steel wire throw-off is provided. This switch is made by the United Electrical Company, Albert Embankment, S.E.

MICA.—The use of mica for electrical purposes has led to a very distinct increase in the demand, and special machinery has lately been devised for getting out the mineral. Some specimens of mica contain iron in sufficient quantity to affect their insulating properties. The whitest kind is usually the best. In Boston several firms are now giving special attention to the preparation of this mineral for electrical apparatus.

THE TECHNICAL EDUCATION BILL.

Whatever may have been the motive of the Government in rescuing this Bill, with several others of greater or less importance, from the massacre which usually overtakes the innocents at the fag end of a session, we are disposed to accept the fact with some satisfaction, if not exactly with pride. The Bill is not one to boast about; but neither is the outcry which has led to its introduction. And in view of the vehement demand for governmental encouragement of Technical Education—a demand which has been fostered by high professional and scientific authority—it is well that some step should be taken to put the matter to a practical test; and for this purpose Sir W. HART DYKE'S scheme is probably as good as any other. We hope, therefore, that nothing may occur to hinder the Government fulfilling their intention in respect to this particular experiment, not because much good can come of it, but because it will enable us the better to judge on independent testimony whether in reality the shortcomings of our industrial system are due to its deficiency in technical knowledge. Those who have been most confident in asserting this as a fact are not wholly disinterested witnesses, and the response to the invitation embodied in the Government Bill, the acceptance of which is everywhere optional, will be a far safer criterion to argue upon. Any given locality may be supposed to know its own wants best, and the local authorities, who alone can set its machinery in motion, are pretty certain to adopt the Bill if it is wanted.

If, on the other hand, the local authorities do not adopt the Bill, we may conclude that in their judgment its provisions would have no beneficial effect on the local industry. The poll which it is necessary to invoke before carrying out their resolution is sure to be in favour of the promoters. School Board as well as Municipal electorates are largely composed of persons who rejoice in getting their children educated at the expense of the minority, and who are not at all likely to scruple about charging another *ism* to the same account. The decision, we repeat, will virtually rest with the representatives of local trades and manufactures, whose well-informed opinion upon the value of this Bill we shall await with much curiosity. They certainly will not be allowed to treat it as non-existent. The Science and Art Department has a direct interest under the provisions of the Bill; and we are sure the Science and Art Department will not lose such an opportunity of expanding its operations. It will prescribe the subjects of instruction, or, at all events, the standards of proficiency; it will, or may, get its own technical schools "combined" with the Board Schools; and it is easy to see that before long the Science and Art Department would have the control of the whole business. Indeed, in practical operation, it seems to us that the school rates may very easily be diverted so as to constitute a subsidy to the Science and Art Department. Again, the managers of any technical schools in the district of a local authority may, under Clause 7 (1), make an arrangement with the local authority for transferring their schools to that authority, which is a further extension of the methods already pursued for extinguishing voluntary schools and throwing the cost of maintaining them on the rates. Thus, there will be no lack of incentive to prompt the local authority to "do their duty"; and it will be strange, indeed, if they resist the pressure.

The powers given under the Act are sufficiently liberal. With the permission of the electorate the local authority may provide separate technical schools for its district, or combine with any other local authority for providing such schools common to the districts of both authorities; or it may contribute to the maintenance, or provision and maintenance, of any technical school; or it may make what other arrangements it sees fit for supplementing, by technical instruction, the ordinary instruction given in any public elementary school in its district. With a view to economy, two or more local authorities may combine for the purpose of carrying out the Act; but this must be with the sanction of the Science and Art Department—a sanction the necessity for which we entirely fail to see, that august body having no interest whatever, but rather the reverse, in sparing the pockets of the local ratepayers. As regards the technical instruction, it is defined as being in the branches of science and art, with respect to which grants are made by the "Department of Science and Art," or "in any other subject which may be sanctioned by that department." It will be seen, therefore, that although considerable latitude is allowed to the local authority in respect to ways and means, its ideas of what kind of technical instruction is required in its district will have to conform to those of South Kensington. This is to be regretted; but London is not included in the Act, or, more correctly, the machinery for applying it there is different; and possibly the provincial mind, knowing less of South Kensington than Londoners do, may hold its authority in higher esteem.

At the first blush, however, "branches of science and art" are not calculated to inspire even the "local authority," we should imagine, with much confidence in their efficiency as a remedy for stagnation in trade. It is to be hoped that the term "in any other subjects" may be broadly interpreted by all the parties concerned. Science and art have their technicalities truly; but science and art do not necessarily include technical instruction—at all events not exactly of the kind which boys attending Board Schools are in need of to get their own living by, and to elevate the character of British workmanship. But perhaps this is not what the prime authors of the Bill are aiming at. We ourselves have never seen a clear statement of what they do aim at. One may, however, hazard a conjecture from the Schedule appended to this Bill. Payment out of the local rates is to be made in respect to no scholar unless or until he has passed the sixth standard; and from the Schedule we gather that before a scholar can be technically instructed—or before his instruction can be paid for, which is, or ought to be, the same thing—he must be able not only to read Shakspeare, write a theme or letter on an easy

Digitized by Google

subject, the spelling, handwriting, and composition of which must satisfy the examiner, but also to pass in arithmetic to the tune of "fractions vulgar and decimal, simple proportion and simple interest." Now, assuming that the technical instruction is going to be a useful reality, it passes one's comprehension to understand why boys who have not learnt these three very big R's should be prevented learning the utilities of their future trade or handicraft. Logically, they are the lads who will depend more on their trade than on the three R's, little or big, and therefore need technical instruction most. But, after all, we do not presume to know for whose benefit precisely the "science and art" is to be given; and we can only desire that the experiment may be speedily tried, and hope that everybody will be satisfied.

CORRESPONDENCE.

NON-POLAR DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have a private letter before me now, touching this correspondence, in which the writer calls attention to a statement by Mr. Preece respecting the inductive effect of a telegraph conductor at Newcastle sensibly affecting another conductor at Darlington, this being, apparently, an argument to convince me of the difficulty of arranging a conductor in a magnetic field without its being influenced thereby. And Mr. Thompson thinks it would be necessary "to construct a pivot conforming with Euclid's definition of a line to get the conductor outside the field without cutting some of the lines of force." Mr. Thompson has laid hold of a misplaced word. I certainly said that by arranging the wire from the pivot in a direction parallel with the axis of the magnet it would be "totally" out of the field. I ought to have said *practically* so. But I would appeal to him and your readers, having regard for the actual and known distribution of lines emanating from a bar magnet, whether such a conductor so placed would not be practically out of the field. It will perhaps be remembered that I took Mr. Thompson on his own ground by examining this question from his own point of view by showing an experiment with both poles of the magnet. That, I submit, proves beyond all doubt that the magnet itself is the movable conductor, while the magnetism is a fixed element. If it were not so the output of current would be the same whether one or both poles were acted upon. I notice Mr. Thompson is silent on this point. I admit that my theory stands or falls by this one experiment. Mr. Snowden asks if the result 1 : 2 was only a prediction on my part; I may say that it was a prediction roughly verified by experiment. I do not say that the result would be practically 1:2, but theoretically so. There is the extra resistance of wire to be taken into account when the two poles are used. Mr. Thompson further informs us that a Gramme ring does not revolve easily in a magnetic field. But the question I asked in my last letter was this:—"Why should not a bar magnet rotate axially through the magnetism as easily as the Gramme ring revolves longitudinally through it?" I said this on the understanding that both were opposed to a mechanical resistance. But why this resistance? That is the question. When a mass of iron is moved in a magnetic field currents are produced in it transversely to the direction of such movement by reason of conductivity, and the mechanical resistance is caused, not by the difficulty of iron passing through the lines of force, but by another kind of force—electricity—being formed in it, which acts on the magnetism. If iron were a non-conductor of electricity it would rotate in the field as easily as a piece of vulcanite. But, says Mr. Thompson, "Why have a core at all?" The advantages of an iron core would appear from the fact that it deflects or concentrates the polar direction of the magnetism or lines of force into the most favourable position to be mechanically acted upon by a movable conductor. In a Gramme ring without an iron core the inside coils would develop an opposing E.M.F. that would be only less than that of the outside coils, as the speed would be less in revolving. The advantage of an iron core in the Siemens armature is not so apparent.—Yours, &c., E. L. VOICE.

6, Betterton-street, Endell-street, W.C.,
August 1st, 1887.

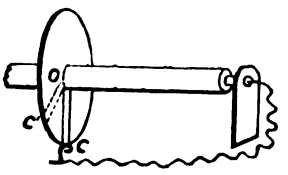
TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sorry that Mr. Snowdon should give me credit for a statement so absurd as that a "a cylindrical magnet rotated on its axis does not excite a current in a stationary conductor situate in its field, while the conductor itself, if rotated in the same way relatively to the magnet, does give a current." The former statement is, of course, quite accurate; the latter is inconsistent with both theory and experiment, and on looking over my letter again, I can see nothing which can have suggested that I entertained such a ridiculous idea.

What I *do* emphatically assert (even at the risk of being stigmatised by Mr. Voice as behind the times) is that no induced E.M.F. is possible in a circuit without a change in the number of lines of force embraced by the circuit—that is, without the cutting by a conductor of lines of force. This "out-of-date theory," otherwise stated, simply affirms that the variation of energy of an electro-magnetic system is proportional to the work expended in deforming it against the electro magnetic forces; and this, again, is a necessary and immediate consequence of the principle (which possibly Mr. Voice considers a relic of antiquity) of the conservation of energy. I have not, unfortunately, access to the copy of *The Electrician* referred to by Mr. Voice; but if he was there successful in upsetting this principle, I venture to say that he brought forward stronger evidence than the experiment of the rotating magnet, and offered a better substitute for the "out-of-date theory" than the explanation (to call it so) which he gives. Unfortunately, this "explanation" is inconsistent with facts, and can be shown to be so by a very simple modification of the apparatus shown in Mr. Voice's diagram.

Mr. Voice says, "Let another conductor be in contact with the other pivot at B, and joined to that leading from A, as in the accompanying figure. The speed of the magnet being the same, the resultant will now equal 2, just double." I hope, for his own sake, that Mr. Voice means us to understand that we shall get double *E.M.F.*, and not double *current*, as one would naturally infer from his language; the strength of the *current* of course depends on the *resistances* of the two circuits.

However, even if Mr. Voice does mean that the E.M.F. is doubled, he is wrong. The speed being the same, the E.M.F. will be the same whether the point C (in Mr. Voice's figure) be joined to the pivot A or to the pivot B, or to both. A galvanometer inserted between the point C and the rubbing contact on the disc will show different deflections in the two cases, or the same according to the values of the resistances in circuit. If, for instance, the resistance of the galvanometer is equal to that of the wire from C to A, and to that of the wire from C to B, the galvanometer deflections will in the two cases (one circuit closed, and both closed) be in the ratio of 3:4.



By a suitable arrangement of the resistances the current may be doubled, but the E.M.F. only by altering the speed.

The real explanation of the production of the E.M.F. is, in reality, a simple matter. If we consider the circuit formed by the half length of the magnet, a *radial element of the disc*, and the outside connections (which for simplicity, though it does not affect the argument, we consider as lying in the vertical plane), we have initially the whole circuit in the vertical plane through the axis of the magnet, as in the figure, and no lines of force pass through the circuit.

But after the magnet has rotated through a portion of a turn we have the state of things seen by the dotted line CC^1

Digitized by Google

The radial element of the disc originally at C has passed to C^1, the rest of the circuit remains as before in the vertical plane through the axis; but the portion O C^1 C is now perpendicular to the axis, and encloses a number of lines of force which vary from zero to a maximum and back again to zero at every revolution. An electromotive force is therefore induced, quite as it should be on the "out-of-date theory."

Mr. Snowdon's idea that the lines of force do rotate (at least unless when prevented by external forces) might, I think, easily be put to the test of experiment.

For a free magnet pole, *e.g.*, a positive pole placed near the magnet, would of course at once move along a line of force to the negative pole of the magnet. Now, if this line of force were rotating round the axis of the magnet, the free pole would share the rotatory movement, and as the result of the combination of the two motions would follow a sort of helical curve terminating at the negative pole of the magnet.

Similarly, a free negative pole would take a corresponding movement, terminating at the positive pole of the magnet. Hence, if a small magnetised needle were brought near the rotating magnet, the movements in opposite directions of each of its poles towards those of the magnet would neutralise each other, but the movements of rotation, being in the same sense in each case, would remain. Hence, the needle, if free to move bodily, would rotate round the axis of the magnet. Such an experiment might, I think, be easily devised. For example, the needle, pivoted vertically, might float on the surface of water in an annular trough, in the centre of which the magnet would rotate on a vertical axis.

Both Mr. Snowdon and Mr. Voice have, I think, rather complicated the discussion by confusing (at least in their language) magnetism and magnetic force, and assuming that magnetism exists necessarily in the medium surrounding a magnetic body. *Magnetic force*, and not *magnetism*, is what exists in the field of a magnet; and to talk of force possessing "inertia," infinite or otherwise, seems to me to be going rather far.—Yours, &c.,

BERNARD P. SCATTERGOOD.

Park-square, Leeds.

ESTIMATES FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been following with much interest the letters that have appeared on "Estimates for Electric Lighting." I quite agree with Mr. Money-Kent that the Electric Lighting Act of 1882 has not been the sole cause of the slow progress of electric lighting.

In many cases this slowness can be traced to men who have undertaken the erection of installations without having a sufficient knowledge of practical engineering—leaving their knowledge of electricity out of the question altogether; men who have not been able to estimate whether an engine they inspected was capable of doing the work required or not.

Now, I venture to think that it is necessary not only that a good knowledge of the laws of electricity should be acquired, but also that every electrical engineer should be a *practical* engineer apart from all else, in order that he may safely judge of what is and what is not required in the estimating and successful carrying out of an installation. Again, what egregious blunders one sees in the estimating of the number of lamps to light a certain area, the size of cable to be used for certain work, &c. This would not be if those who tender were thoroughly practical men.

I scarcely think that Plonmel's figures can be carried out in practice, because buildings vary so much in shape and form, and in all cases the light is not required to be uniform.

For instance, a place of entertainment requires the light concentrating more particularly on the platform, as was the case here two years ago when the National Eisteddfod held their annual meeting. And here we will have a word about tenders and consulting electrical engineers.

I was called in by the committee of the Eisteddfod to give my opinion as to the number of lights required to light the pavilion (the area of which was 21,312 square feet), and also to advise as to the disposition of the lamps. I estimated that it would take 177 16 candle-power lamps to light it brilliantly, but under the circumstances 133 might do, as most of the light was required near the platform.

Tenders were invited, but no specifications given. Only two were received; one from a branch of one of the largest companies in the kingdom, and the other from a private firm. The former proposed seven 1,200 candle-power arc lamps inside and three outside; the latter sixty 16 candle-power incandescent inside and three arc lamps outside—a most remarkable difference in the candle-power estimated. Cost of former company to be £58; cost of latter to be £27. 10s. I pointed out to the committee that the light would be perfectly inadequate if they used only sixty 16 candle-power lamps; but they were assured, on the other hand, that the firm would guarantee them sufficient light. It ended thus:—The committee put a gang of men to work on Sunday to get the gas in, thus bringing the profession of electrical engineering into contempt, and making "electric light" a bye word for darkness.

I could mention many other things; but I think I have said sufficient to show that a knowledge of practical engineering is indispensable; that a perfect knowledge of the area a lamp will light satisfactorily is required; that the lowest tender is not always the cheapest; and that a consulting electrical engineer is not always thought to be right when those who are employing him, or asking his advice, think they know the most, or are afraid to go to the necessary cost to do the work properly.—Yours, &c.,

G. WILSON.

Aberdare, August 2nd, 1887.

A NEW EDISON SYSTEM OF DISTRIBUTION.*

It has come to be recognised that if high-tension currents can be employed for electric lighting and other purposes, with the economy in copper which they permit of, but without bringing the wires carrying the high potentials within buildings where they are subjected to handling, and where contact with them is liable to lead to accident, the scope of electrical distribution would be greatly enlarged. The endeavour to accomplish this object has given rise to a number of systems of late, most of which have been based on the alternating or interrupted current and the transformer to reduce the potential from the distributing wire to the house wire.

In order to achieve the same object with the continuous current Mr. Edison has recently devised a system in which a high-tension circuit is employed, and which may in a certain sense be called a multiple-series system on a large scale, with special arrangements for keeping the potentials in each multiple branch constant. In carrying out his idea, Mr. Edison uses a divided source of electricity of high tension consisting of two or more dynamos connected in series placed in a suitable building at a place where power may be produced economically. A circuit extends from this source of power to the various sub-stations, at each of which feeding circuits are taken off, which extend to a district to be supplied with current. All these sub-stations are in series, and from the main circuit conductor between the stations compensation conductors extend, which are connected with the points of division of the source of supply.

At each sub-station indicators and regulators are provided by means of which the electrical condition of the circuits extending from them is indicated and regulated, and from each sub-section a circuit extends to the main station or source of supply, with which circuits are connected indicators, in accordance with whose indication the generators are regulated according to the requirements of the distance supplied from each sub-station.

In the diagram the system is shown in which the districts are arranged on the three-wire system, but the arrangement is equally applicable to the two-wire system.

The method is particularly applicable to cases where there is a very large area to be lighted or supplied with current from a single source.

In the Figs. A, A^1, A^2 and A^3 are dynamos all connected in

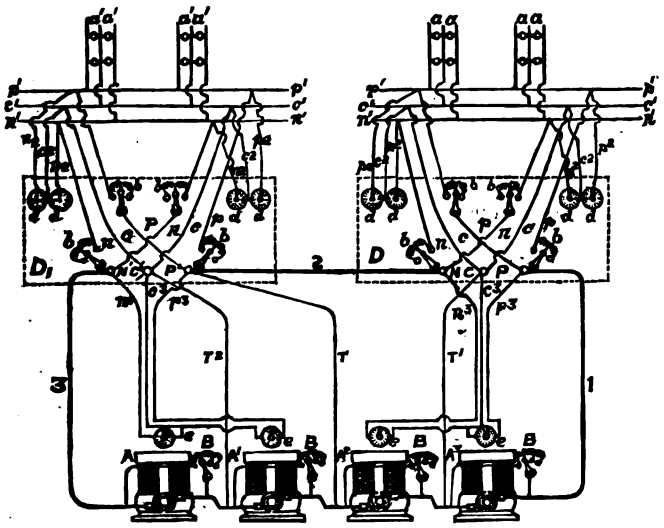
* From the New York *Electrical World*.

Digitized by Google

series and situated at a point where the necessary power to operate them can be cheaply produced, and which may be for that purpose situated, if necessary, at a considerable distance from the places to be supplied, since the current generated by the series of machines has a high tension, and can therefore be economically conveyed by conductors of small mass. Each generator can be regulated separately by means of the adjustable resistances B B, placed in the shunt field circuit of each machine.

From the terminals of the series of machines a circuit, 1, 2, 3, is extended to D and D^1, which represent sub-stations to which the circuit extends. The dotted rectangles indicate rooms or places into which the conductors are run, and in which the connections are made and the indicators and regulators are placed. In the station P the conductor 1 is brought to a positive terminal point, P, and from a negative terminal point, N, the conductor 2 extends to the next sub-section, and there is also a third terminal point, C. From the sub-station extend two feeding circuits *p*, *n*, *c*. The conductors *p* extend from terminal N, and conductors *c* from terminal C, and these conductors are all connected respectively with the positive, negative, and compensating circuit conductors *p' n' c'*, with which the lamps *a a* are connected in multiple series on the three-wire system.

Each of the feeding conductors *p*, *n*, is provided with an adjustable resistance *b b*, by which the two sides of the sub-system are regulated to keep the same constant pressure at all points on the lighting circuits, thus regulating for unequal distribution or changes in the number of lamps in circuit. This regulation is effected in accordance with the showing of indi-



cators *d d*, connected across the conductors of three-wire indicating circuits $p^2 n^2 c^2$, one of which extends back from the terminals of each feeding-circuit into the sub-station, and which continually show the pressure at the points where the feeders are connected. The sub-station D' is similarly arranged and equipped, the conductor 2 being carried to the terminal point P' and the conductor 3 from the main source to the terminal N', and the feeders extending from terminals P', N', and C', and supplying lamps *a' a'*, and provided with indicating and regulating apparatus precisely as explained with reference to the other station. It will be seen that the conductor 2 connects the two districts supplied from the two sub-stations in series with each other, and with the generators at the main station. From any point on the conductor 2 between the sub-stations a conductor T extends to the middle point of the series of generators, by which a divided source of electricity is produced, at whose point of division the compensating conductor T is connected. The conductor T is shown as extending from the terminal point P' in sub-station D'. The effect is evidently the same as though it were connected anywhere along the line 2 between the sub-stations.

From the terminal point C in station D a conductor, T', extends, which is connected between the generators A^2 and A^3—that is, at the middle point of one of the divisions of the source—and from C' in station D' a similar conductor, T^2, extends and is connected between generators A and A', the two divisions of the source being thus themselves divided, or, in other words, the source being thus subdivided into four sub-divisions. Thus the two districts form a compensating or three-wire system, having a divided source and a compensating conductor, while each district is itself a three-wire system having a divided source and a compensating conductor. The lamps of the two districts are in multiple series with each other—that is, any two lamps, *a a* in series in district D, are in series with two other lamps, *a' a'*, in district D'. There are, therefore, four lamps in series, and hence high-tension currents and small conductors are employed. At the same time, all the lamps are independent. In each sub-system, when the number of lamps on the two sides becomes unequal, current flows in one direction or the other on conductors *c* and T' or T^2 to maintain the balance, and if the number of lamps in one sub-system differs from that in the other the balance is similarly preserved by the compensating conductor T.

As stated, the adjustable resistances at the sub-stations are employed to keep a constant pressure at all feeder terminals, thus regulating for unequal distribution or changes in the number of lamps in circuit in different parts of the district. Indicating circuits also extend from the sub-stations to the main station, each of which consists of three conductors, p^3 n^3 c^3, including indicators *e e*, by means of which the condition of each side of each sub-system is continually shown, and in accordance with which the generators are regulated together or separately to regulate the whole current supplied to the entire system, or that supplied to each sub-system or that supplied to each side of each sub-system. It is evident that there may be any desir d number of sub-stations and districts supplied, the number of generators at the station being correspondingly increased, so that there will be one or more generators for each side of the sub-system, and conductors being run from between the sub-stations to the points of division, and from the middle terminals of the sub-stations to the poin's of subdivision of the source. The generators comprising the high-tension source need not necessarily all be placed in the same building or at the same place; but they may be placed at two or more different points, they being, however, always connected in series by conductors extending between the different points.

In the system above described economy is attained not only in conductors but in other ways also, in the matter of renting or purchasing property for stations, for instance; for the main station may be placed at a distance from the thickly settled areas to be illuminated, at a point where rents are low or property cheap, while for each of the sub-stations only a small room is necessary, which can be cheaply obtained, it being necessary only to have room enough for the indicators and adjustable resistances. A single attendant is kept at each sub-station, whose only duty is to observe the indicators and adjust the resistances accordingly.

THE BRUSSELS 1888 INTERNATIONAL EXHIBITION.

The following is the schedule of the electrical section of this exhibition under which the prizes and medals are to be awarded:—

Sub-division 47a.—President: ERNEST ROUSSEAU.—"The study and instruction of electrical science; instruments of measurement; scientific application of electricity; lightning conductors and lightning protectors."—1. Lightning conductors. 2. Processes of testing a lightning conductor. 3. Means of ascertaining the value of a battery. 4. Laboratory tests of a conductor intended for an overhead line. 5. Instrument or means of measuring telephonic currents. 6. Treatises on the science or application of electricity. 7. Industrial ampere-meters for continuous currents. 8. Industrial ampere-meters for alternating currents. 9. Industrial voltmeters for continuous currents. 10. Industrial voltmeters for alternating currents. 11. Ampere-hour meters. 12. Watt meters. 13. Collection of measuring instruments for laboratories. 14. Measuring apparatus constructed on a new principle, or exhibiting an improvement on existing apparatus. 15. Photometry by means of electricity. 16. Apparatus for measuring power absorbed by magneto or dynamo machines.

Sub-division 47b.—President: M. F. DELARGE.—"Motors and dynamo electrical machines; transmission of motive power to a distance; distribution of electrical energy, transformers."—17. (*a*) Electric light dynamos, output not exceeding 2,000 watts; (*b*) ditto, not exceeding 10,000 watts;

Digitized by Google

(c) ditto, not exceeding 10,000 watts; (d) dynamo machines for light-houses; (e) dynamos to replace batteries in telegraph offices. 13. (a) Transmission of motive power to a distance, &c.; (b) systems of distributing electrical energy.

Sub-division 47c.—President: M. BANNEUX.—"Telegraphy, telephony, wires, and cables."—19. The most practical system of light lines and apparatus (either telegraphic or telephonic) for communicating with out-posts. 20. Insulators (a) for telegraph lines; (b) for telephone lines. 21. Overhead conductors (a) for telegraph lines; (b) for telephone lines. 22. Metallic posts for lines (a) in the open country; (b) in towns. 23. Systems for preservation of wooden posts. 24. Stays and struts (metallic) for posts. 25. Submarine cables (a) for telegraph lines; (b) for telephones. 26. Lightning protectors 27. Telephones; (a) for private lines; (b) for public service. 28. Microphones; (a) for private lines; (b) for public service. 29. Telephone exchanges; (a) for private lines; (b) for public service. 30. Simultaneous telegraphy and telephony on one wire. 31. Multiplex telephony. 32. Commutators for telegraph lines. 33. Telegraph apparatus for offices of moderate importance. 34. Fast-speed telegraph apparatus for single transmission. 35. Telegraph apparatus, multiple transmission. 36. Apparatus for working submarine cables of large capacity. 37. Relays. 38. Telegraph calls. 39. Remedies for induction on telephone lines. 40. Systems of telephone stations connected on a single line wire with either earth or wire returns. (The stations must be able to communicate with each other, and also through a central exchange with other lines.) 41. Automatic telephone exchange apparatus. 42. Telephone relays. 43. Means of connecting a metallic circuit line with an earth return line. 44. Protection of insulated cables from fire. 45. Means of preventing the abnormal heating of conductors.

Sub-division 47d.—President: M. WYBAUX.—"Arc and incandescent lamps."—46. Arc lamps (a) of great power; (b) of moderate power, 500 to 2,000 candles (c) of low power; (d) arc light carbons. 47. Incandescent lamps. 48. Electric lamps of any other type. 49. (a) Systems of lighting mines, submarine lamps, &c., (b) portable lamps. 50. Supports for public lamps.

Sub-division 47e.—President: M. WAFFELAERT.—"Batteries, accumulators, various industrial applications, electro-chemistry, electro-metallurgy, railway signals, &c., &c."—51. Batteries for telegraphs; (a) continuous currents; (b) intermittent currents. 52. Batteries for telephones. 53 Ditto for movable telegraph stations. 54. Dry batteries. 55 Batteries for domestic electric lighting. 56. Thermo-electric piles; (a) for domestic electric lighting; (b) for other purposes. 57. Batteries for lighting sailing ships. 58. Accumulators. 59. Electric clocks and systems of distributing time. 60. (a) Apparatus for indicating temperature at a distance; (b) automatic fire alarms; (c) public fire alarms. 61. Speed regulators. 62. Extracting metals from their ores. 63. Processes of working metals. 64. Applications of electricity to industrial chemistry. 65. Applications to railroads; (a) communication with moving trains; (b) intercommunication on trains. 66. (a) Applications to the block system; (b) actuating signals at a distance; (c) applications to interlocking systems; (d) actuating barriers at a distance. 67. Electric breaks. 68. Indicators of position of trains and other similar applications, such as indicators of water level. 69 (a) Lighting trains; (b) heating trains. 70. Electric traction; (a) by accumulators; (b) from fixed stations, by existing rails, by a special rail, by overhead conductors; (c) on primary and secondary lines, and on tramways; (d) telpherage. 71. Registering variations of velocity of a motor. 72. Electric governors. 73. Firing shots in mines; (a) by high-tension fuses; (b) by mean tension; (c) by low tension. 74. (a) Electric rifles; (b) firing artillery; (c) training artillery. 75. Electric torpedoes, fixed; torpedoes steered or propelled by electricity. 76. A prize is offered for the most remarkable invention in electricity not coming under any of the above heads.

DESCRIPTION OF THE ELECTRIC LIGHT ON THE ISLE OF MAY.*

BY DAVID A. STEVENSON, B. SC., F.R.S.E, M. INST. C.E.

The lighthouse situated on the Isle of May, at the mouth of the Firth of Forth, has recently been lighted with electricity; and as this light, besides being, the author believes, the most powerful in the world, possesses several novel features, he has the pleasure of offering the following notes regarding it, trusting that they will prove of interest in connection with the visit to be made to the lighthouse on the occasion of the present meeting.

The Isle of May was originally lighted in 1636 with an open coal fire. In 1816 the Commissioners of Northern Lighthouses, having previously purchased the island with the right to levy tolls for the lighthouse, altered the light to argand lamps with silvered parabolic reflectors. In 1836 it was converted to the dioptric system, with a first order fixed light apparatus, and a four-wick burner; and on 1st December, 1886, the electric light was substituted, and shown in connection with a dioptric condensing apparatus. For the last fifteen years the Commissioners of Northern Lighthouses, acting under the advice of their engineers, Messrs. Stevenson, had been anxious to establish an electric light on the Scottish coast; but it was not till 1883 that the Board of Trade were able to sanction the expenditure, and suggested its introduction at the Isle of May on the ground that "there was no more important station on the Scottish shores, whether considered as a landfall, as a light for the guidance of the extensive or important trade of the neighbouring coast, or as a light to lead into the refuge harbour of the Forth."

Notwithstanding the difficult access and isolated position of the Isle of May, distant five miles from the Fife shore, which is the nearest land, it was resolved to accept the view of the Board of Trade, and to introduce the electric light there. The necessary plans and specifications were accordingly prepared by Messrs. Stevenson; and the works, begun in June, 1885, were completed, and the new light installed by 1st December, 1886.

It was originally intended by Messrs. Stevenson to use the Brush compound-wound Victoria dynamo, giving a continuous current, and supplying a single automatically fed arc lamp with the positive carbon *below*. This system was selected as being at once cheaper, and as giving a stronger light-power for the engine-power applied, than the magneto-electric machines, which had hitherto, with success at least, been exclusively used in lighthouses. The placing of the positive carbon below was adopted in order that the strongest light might be thrown upwards, so as to be dealt with by the upper part of the dioptric apparatus, and thus be more effectively utilised. The Brush Company at once set to work to produce a lamp of the above description, giving, with a current of 100 amperes and 70 volts, a light of 30,000 candle-power in the horizontal line, steady and suitable for burning in a lighthouse. This unfortunately they were unable to accomplish, even after numerous trials; and at last, as the buildings on the island were nearly completed and it became necessary at once to procure reliable apparatus, recourse was had to the more expensive alternate-current machines of De Meritens, which, though not so powerful, are admirably steady in working, and had given excellent results in several lighthouses, and also at the South Foreland experiments.

The generators at the Isle of May are two of De Meritens' alternate-current magneto electric machines of the L type, and are of the largest size hitherto constructed, weighing about 4½ tons each. The induction arrangement of each machine consists of five sets of twelve permanent magnets, sixty in all; and each magnet is made up of eight steel plates. The armature, 2ft. 6in. diameter, is composed of five rings with 24 bobbins on each, arranged in groups of four in tension and six in quantity; it makes 600 revolutions per minute.

With the circuit open each machine develops an electromotive force of 80 volts measured at the distributor, and with the circuit closed through an arc 40 volts. An average current of 220 amperes is developed, thus yielding an electrical energy of 8,800 watts, or 11·7 horse-power in the external circuit. The five rings are so arranged that one-fifth, two-fifths, three-fifths, four-fifths, or the whole of the current of a machine can at pleasure be sent to the distributor for transmission to the lantern; and, further, the two machines can be coupled, and the full current from both be employed. The machines are placed in the engine room bolted down to concrete foundations, and driven from a counter-shaft.

The engines are a pair of horizontal surface-condensing steam engines, each with two cylinders of 9 inches diameter and 18 inches stroke, making 140 revolutions per minute, and each indicating 17·7 horse-power with 40lb. steam pressure above atmosphere and 11lb. vacuum. To provide against accident or failure of water supply, they have been arranged so as to be capable of being worked either condensing or non-condensing. Either of them is sufficient to drive one machine, the other engine being idle; or the two can be used together for driving both machines in thick weather. The steam to both cylinders is regulated by an equilibrium throttle-valve, which is controlled by a high-speed governor, adjusted for the engine to run at the normal speed of 140 revolutions per minute. Single, in place of compound, engines were adopted, because they are less complicated and better suited for the less skilled attendance of ordinary lightkeepers. Probably also greater regularity in driving has thus been secured, which is of course a matter of the greatest importance in electric lighting, especially where, as is the case, there is only a single arc-lamp in the circuit forming the resistance. The result has been eminently satisfactory; and the engines, which were built by Messrs. Umpherston, of Leith, are a most excellent piece of work.

There are two steam boilers, of which only one is in use at a time, the other being spare. Each is 20ft. long, and 5ft. 6in. diameter, with one furnace flue 3ft. diameter and 8ft. long, having six cross Galloway water tubes. The shells are of best best ⅜in. steel plates, with the longitudinal joints double riveted; and they were tested up to 110lb. per square inch, the working pressure being 40lb. The feed is principally rain water collected from the roofs and the pavement of the court; but water can, if required, be taken from the small loch, which is also used for condensing purposes. The coal consumption is 1 cwt. per hour of lighting, which includes banking the fires during the day.

The current generated in the engine room is conveyed to the lantern by leads, which consist of copper rods of 25 millimetres or 1in. diameter, covered with a double waterproof wrapper. This is the first time that copper rods have been used for conducting the current for lighthouse illumination. They are constructed in 14ft. lengths, the joints being formed with a zigzag scarf screwed up tightly by gunmetal coupling-boxes with four bolts in each. They are carried by timber bearers, placed in a groove made for them in the side of a concrete wall running from the engine room to the tower. The total distance to the lantern is 880ft. Several bends are introduced to allow for expansion and contraction due to changes of temperature. The loss in the leads was expected not to exceed one-sixth of the total energy generated; but it is considerably more than this, amounting to at least one-fifth.

The lamps, of which there are three, one in use and two spare, are of the Serrin-Berjot type, with some modifications—notably, the shunt or bye-pass, first introduced in the South Foreland experiments on the suggestion of Dr. Hopkinson, whereby a large percentage of the current goes direct to the lower carbon, and only an amount sufficient to regulate the carbons is passed through the lamp. This is a great improvement, and prevents injury to the lamp from heating. The weak point about it, in the lamps sent to the Isle of May, was that the contact between the lower carbon-holder and the bye-pass, being necessarily a sliding contact, was

* Paper read at the meeting of the Institution of Mechanical Engineers.

Digitized by Google

effected by copper-wire brushes; and these were found to wear out rapidly. On the suggestion of Mr. Munro, the engineer in charge of the station, a simple form of mercury contact has been substituted, and works quite satisfactorily.

The carbons in use are 40 millimetres or 1·6in. diameter; but if desired 50 mm. or 2in. carbons can be used when both machines are running. They are Siemens's make, and have a soft central core of pure graphite, which has the effect of causing them to burn with greater regularity and steadiness than they otherwise would, and prevents a crater from forming and remaining at one side. The rate of consumption of the 40mm. carbons is 1¼in. per hour, or 2in. including waste. The power of the arc is estimated at 12,000 to 16,000 candles when one machine only is running.

The dioptric apparatus, which was manufactured from Messrs. Stevenson's designs by Messrs. Chance, of Birmingham, is of a novel description, the condensing principle being carried further than in any apparatus previously constructed. This principle consists in darkening certain sectors by diverting the light from them, and throwing it into the adjoining sectors so as to reinforce their light. Thus the power of the light is increased in proportion as the dark arc is increased. Although interesting we must pass rapidly over this portion of the paper, just mentioning that an arrangement is made for dipping the light during fog which has not yet been used; but as soon as the lightkeepers, who, with the exception of the engineer, were the ordinary keepers in the service and knew nothing of electric lighting, have become thoroughly familiar with their duties, it is intended to introduce it, and probably in the same way to employ a less powerful current, and say 25 mm. or 1in. carbons in very clear weather; while both machines with 50 mm. or 2in. carbons will be used in very thick weather. The lamps can by a carefully designed arrangement be changed in eight seconds.

The resulting beam of light from this apparatus is about three million candles when one machine is in use, and with both machines six millions; that is, about 300 and 600 times more powerful than the old fixed oil light. When the three-wick oil lamp is put in the focus of this apparatus the emergent beam is more powerful than the old fixed oil light with a four-wick lamp, which was 9,446 candles. The light has been picked up and recognised by sailors at forty and fifty miles off, by the flashes illuminating the clouds overhead, although the geographical range of the light is only 22 miles.

The engine room is connected by telephone with the light room, and the houses of the keepers are connected by air whistles or electric bells with either the light room or the engine room.

The new buildings, engines, electric machines, lamps, &c., have cost £15,835; and the buildings, lantern, &c., previously on the island, which have been utilised, may be valued at £6,600. Thus the total cost of the installation may be taken at £22,435; and the cost of maintenance will not exceed £1,050 per annum. These figures are very moderate, considering the great power of the light, and the isolated position of the lighthouse. To compare the cost of this installation with what it would have been if oil were the illuminant, there must be added to the above £6,600 for buildings, a sum of £2,925 for the cost of the apparatus and machine, &c., making a total of £9,525, while the cost of maintenance would have been £330 per annum. Taking these figures, and adding to the maintenance 3½ per cent. on the original outlay, it is found that while the oil light would cost 3·49 shillings per hour and 0·00017 penny per candle-power per hour, the electric light costs 9·66 shillings per hour or 2¾ times more, and 0·000038 penny per candle-power, or less than one quarter of what the oil light would cost per candle-power. This is taking the electric light power of one machine.

Surprise has frequently been expressed by masters of vessels, and by residents on the neighbouring shores who live in view of the Isle of May light, that this light, which is so extremely brilliant in clear weather as to cast shadows at a distance of ten and fifteen miles, is so cut down by fog that some even go the length of believing the old oil light was better in fog. All who have experience of the electric light are quite prepared for the first part of this statement; while the last, it need hardly be said, is a mistake, inasmuch as the electric arc has been proved both by experiment in natural and artificial fog, and also by observations on existing lighthouses lighted by electricity, to be in all circumstances of weather the most penetrating. Every night at twelve o'clock the lightkeepers at St. Abbs Head, 22 miles distant, where there is a first-order flashing light and one of the most powerful oil lights in the service, observe the Isle of May light, while the keepers there also observe the St. Abbs Head light. The result of the last five months' observations is that the Isle of May light is seen one-third oftener from St. Abbs Head than the St. Abbs Head light is seen from the Isle of May. It is perfectly true, however, that the superiority which is so apparent in clear and rainy weather is very much reduced in hazy weather, and practically disappears in very dense fog. Looking to this fact and to the large first cost and annual maintenance, the author feels that the conclusion arrived at by the Trinity House is sound, namely, that electricity should be used only for important landfall lights.

If, however, the most powerful light is desired independently of cost, then the electric arc has no rival. And if the further expense is to be incurred of introducing biform, triform, quadriform, or even double quadriform lights, then the electric light is better adapted than any other illuminant, because, on account of its focal compactness and other properties, it can be so dealt with by suitably designed dioptric apparatus that the whole light evolved is effectually utilised. This is not the case with the large gas or oil flames generally used in the multiform system, in which, for this and other reasons, a considerable loss of light is incurred. Moreover, the coolness of the electric arc renders multiform lights really practicable with electricity, which can hardly be said to be the case either with gas or with oil.

The author of this paper, however, inclines to the use of hyper-radiant apparatus.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis:—

RECHERCHES SUR LA CONDUCTIBILITE GALVANIQUE DES ELECTROLYTES.*

BY SVANTÉ ARRHENIUS.

(*Continued from page 215.*)

Thus much is a meagre account of the First Part of the complete memoir. I now pass to the far more striking Second Part, and shall find it necessary to give a much fuller, and in many places verbatim, report.

I am not able to judge as to how much is original and new, as I am but slightly acquainted with work of previous writers on similar subjects, nor am I at all confident how far the hypotheses made by the author are perfectly legitimate. So far as I am able to judge, however, and making allowance for inadequacy of data and somewhat hasty generalisation, the paper seems to me to be a distinct step towards a mathematical theory of chemistry.

The title affixed to it is "The Chemical Theory of Electrolytes," but it really is an attempt at "an electrolytic theory of chemistry."

SECOND PART.

THÉORIE CHIMIQUE DES ELECTROLYTES.

89 pages. Abstract and translation by OLIVER LODGE. [*Remarks by the Abstracter in square brackets.*]

§ 1. Ammonia considered as an electrolyte.

Kohlrausch has shown that a solution of ammonia, as regards conductivity, behaves differently from all other bases. It is a much worse conductor than potash, and its exponent of dilution is not much bigger than 1 [*i.e.*, its conductivity, instead of increasing anything like so fast as concentration, scarcely increases at all]. Kohlrausch guesses that the cause of this is the prevalence of NH_3 in solution instead of NH_4HO. Probably dilution increases the supply of NH_4HO, and therefore assists conduction almost as much as it for other reasons weakens it. This would explain the peculiarly small exponent of dilution.

(14) *The conductivity of ammoniacal solution is caused by a small quantity of* NH_4HO, *which is increased by dilution.*

[I think it most rash to make definite statements like this on such a slender basis of fact.]

§ 2. Case of acids; activity.

Acetic acid has the same properties as ammonia; so has boric acid. Tartaric and oxalic have small exponents of dilution. Probably the behaviour of these acids, as well as of ammonia, is analogous to that of HCl, which only conducts in presence of water. Sulphuric, nitric, phosphoric, behave in the same way. Hence—

(15) *The aqueous solution of any hydrate* is composed of two parts besides the water, viz., an active (electrolytic) part and an inactive (non-electrolytic) part. The three constituent parts of the solution form a system in chemical equilibrium, such that dilution increases the active and diminishes the inactive portion.*

How the inactive and active portions differ is not certain, perhaps only physically. Perhaps the active part is a compound of hydrate and solvent.

To fix ideas we can introduce the notion of a coefficient of activity, defined thus:—

The coefficient of activity of an electrolyte is a number expressing the ratio of the number of ions which are really in the electrolyte, to the number of ions which it would enclose if the electrolyte were totally transformed into simple electrolytic molecules.

[This "coefficient of activity" is evidently the same thing as what, in accordance with dissociation ideas of electrolytic conduction, I called† the "dissociation ratio," *i.e.*, the relation between the number of atoms taking part in conduction to the whole number present. It may turn out that this ratio is unity, but it is in any case well to determine it, and the idea of Arrhenius that it is upon that that chemical activity and rapidity of interchange depends seems to me important.]

§ 3. Hypothesis of Williamson and Clausius, and consequences thereof.

[The continual interchanges of atoms supposed to occur among the molecules on this view of conduction are here regarded as circular electric currents. References to the original statements of the hypothesis are given as follows:—Williamson, Liebig *Ann.*, Vol. 77, p. 37 (1851); and Clausius, Pogg. *Ann*, Vol. 101, p. 347 (1857)].

§ 4. Deduction of some electro-chemical laws (16)—(20).

[*E.g.*, Faraday's laws. I omit this section because it is not much use deducing laws like these from an hypothesis. The Williamson-Clausius hypothesis is of course in harmony with the fundamental laws of the subject, otherwise it would have been pretty soon abandoned. Probably the object of the author is to show how readily the known laws can be built up from one simple foundation. One statement deduced from this hypothesis is worth quoting (*see* also *Wiedemann, Elek.*, Vol. II., p. 924).]

(20) *Every body which acts chemically by double decomposition on an electrolyte is itself an electrolyte, as well as the products of the decomposition. Therefore water, alcohol, aldehydes, &c., &c., are electrolytes and therefore conductors.*

* For "hydrate" always read *hydrogen compound, either base or acid.*

† On page 756 of last year's B. A. *Report*, Aberdeen.

Digitized by Google

[The *a priori* manner in which this statement is made is striking ; so is the note immediately following.]

"On this subject people have disputed for some time. They often attribute the feeble conduction observed in these bodies to traces of saline impurity."

§ 5. Relation between conductivity and chemical power of acids and bases.

(21) *The molecular conductivity of the active part of an acid (in dilute solution) is constant and independent of the nature of the acid.*

For if the chemical formula of an acid is HR, its molecular conductivity, according to Kohlrausch, is $h+r$. Now the molecular conductivity of dilute salts with the same metal, MR, MR', &c., is the same ; hence $r=r'=$&c. And therefore it follows that for acids also the molecular conductivity of HR, HR', &c. is the same. A corollary is—

(22) *The more a dilute acid solution conducts, the greater is its active part.*

Similar propositions may be stated for bases.

[The author then goes on to consider the idea of coefficients of activity more particularly in the light of the Williamson-Clausius view, and he gives reasons for supposing molecular conductivity and coefficient of activity to be closely related, and indeed proportional to one another. He then says, let them be defined to be equal. A list of molecular conductivities for acids, bases, and salts from the results of Kohlrausch is supplied, and it is pointed out that the best conducting acids are the strongest. Appeal is made to the results of Berthelot, Thomson, and Ostwald in support of this.]

"Thus we believe we have proved that for acids and bases galvanic activity is accompanied by chemical activity," and probably non-electrolytes have no direct chemical action. *Cf.* Gore on the inactivity of anhydrous HCl.

§ 6. Double decomposition.

[This section is the key to the whole, and I had best translate it in full.]

Suppose two electrolytes, A B and C D, are dissolved in an inactive solvent. Circular currents pass in the solution [*i.e.* Williamson-Clausius atomic interchanges occur], whereby the bodies A D and B C are formed. If the coefficients of activity of all four bodies A B, C D, A D, and B C were equal, they would all be present in the same quantity, viz., half an equivalent of each, provided the original substances were in equivalent proportions. And in any case an equilibrium would establish itself, the rate of formation of each substance being equal to its rate of destruction. Now the coefficient of activity of a body indicates that fraction of the body which at any one time participates in the circular currents [*i.e.* is ready for interchange]. If then this coefficient for A B is α, and if m equivalents of A B exist in solution αm expresses the number of equivalents of A B which at any moment take part in the circular currents.

One could figure to oneself the process of double decomposition in the following manner. The ions of active molecules rotate round one another. Then, considering the molecules A B, the ion A moves with a certain velocity in the neighbourhood of B until it comes near another ion, B', after which it follows B'. The molecule A B exists until this happens.

As now, from the preceding, the conductivity of the active parts of all salts is the same—that is to say, according to M. Kohlrausch, the velocity with which the ions move relatively to each other is independent of the nature of the salt, and only depends on the strength of the current—it is natural enough to suppose that the said velocity is the same for all salts, even when the strength of the current is zero. [This is rather an overstraining of Kohlrausch's results, but it may pass as a first approximation any way.]

Suppose, moreover, the mean distance at which A need find itself from B' in order that it may abandon B and attach itself to B' is the same for all B ions, whatever their nature (as is probably the case in gases). In this case M. Clausius has shown that the mean path of the cation A between the moment of encountering B and B' is—

$$l=\text{const}/n,$$

where n is the number of an ion in unit volume.

True, M. Clausius has given this proof for the case where the paths are rectilinear, but according to the premisses of the demonstration it is equally valid if the path is a broken line or any other form. Suppose, for simplicity, that the B ions are motionless ; then, from what precedes, the mean time of existence of the molecules A B is—

$$t=\frac{l}{v}=\frac{\text{const}}{n\,v},$$

v being the mean velocity of an A ion. So, in unit time, of m molecules A B, a number equal to—

$$\frac{m}{t}=\mathrm{K}\,m\,n$$

are destroyed (v being the same for all electrolytes, is included in the constant K). In reality the B ions are also moving, but since v is the same for all, the only effect will be to change the constant K in such a way as to leave it, nevertheless, the same for all salts.

In the same way we can show that if p is the number of A ions, and q the number of B ions in unit vol., the number of molecules A B *formed* in unit time is

$$\mathrm{K}\,p\,q.$$

Hence the number of A B molecules at the end of unit time in excess of those at the beginning—that is to say, the velocity of the reaction by which A B is being formed—is

$$\mathrm{K}\,(p\,q-m\,n).$$

If the hypotheses supposed in the foregoing are only approximately true, the above deductions are no more so. The effect would be to multiply the number $p\,q\,m$ and n by different factors, so that the general aspect of the above-deduced expressions will be only slightly modified. The same thing can be said for the equations we deduce in the sequel. However, as in the actual state of science it is impossible to judge of the validity of these hypotheses, and as they have a certain degree of probability, and of all hypotheses are the simplest we can imagine, it is my intention to prove that the deductions which it is possible to draw from what has just been said are compatible with experimental facts—facts of which we thus give a certain explanation. But with the progress of science it is possible that one will see the necessity of modifying these hypotheses ; the general reasonings will persist nevertheless, as well as the conclusions drawn from them.

Now, suppose we have four electrolytes, A B, A D, C B, and C D, intermingled ; let the number of equivalents of each existing at a given moment be m, q, p, n, respectively, and the corresponding coefficients of activity α, β, γ, and δ, the velocity of reaction will be, according to the foregoing,

$$\mathrm{K}\{(m\alpha+q\beta)\,(m\alpha+p\gamma)-m\alpha\,(m\alpha+q\beta+p\gamma+n\delta)\},$$

an expression which transforms itself into the following :—

$$\mathrm{K}(q\beta\,.\,p\gamma-m\alpha\,.\,n\delta) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The state of equilibrium will be attained when the velocity of reaction is nothing. If then m originally equalled 1, and a quantity x of the body A B has been transformed, the final state will contain $1-x$, $n-x$, $q+x$, $p+x$, equivalents of the bodies A B, C D, A D, C B, respectively. The equation expressing equilibrium will thus be—

$$(1-x)\,(n-x)\,\alpha\,\delta=(p+x)\,(q+x)\,\beta\,\gamma \quad . \quad . \quad . \quad . \quad (2)$$

or, if p and q are zero, a case often realised in experience—

$$(1-x)\,(n-x)\,\alpha\,\delta=x^2\beta\,\gamma \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2\text{A})$$

Now introduce the following definition :— . . . Two electrolytes like A B and C D, which have no common ion, are to be called *conjugate* ; and two like A B and A D, or A B and C B, are to be called opposite.

(23) *It is pretty clear that, as soon as the relative quantities of the ions, A B C D, are given, the final result is independent of their original form of combination, whether A B and C D, or A D and C B, or any other form.*

This proposition is sufficiently natural to need no proof. Moreover, it has been verified by the work of MM. Guldberg and Waage and Ostwald.

Solving equation (2) we get—

$$x=-\frac{\alpha\,\delta\,(n+1)+\beta\,\gamma\,(q+p)}{2\,(\beta\,\gamma-\alpha\,\delta)}\pm\sqrt{\left\{\left(\frac{\alpha\,\delta\,(n+1)+\beta\,\gamma\,(q+p)}{2(\beta\,\gamma-\alpha\,\delta)}\right)^2+\frac{\alpha\,\delta\,.\,n-\beta\,\gamma\,.\,q\,p}{\beta\,\gamma-\alpha\,\delta}\right\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

or for the special case when q and p are zero—

$$x=-\frac{\alpha\,\delta\,(n+1)}{2(\beta\,\gamma-\alpha\,\delta)}\pm\sqrt{\left\{\left(\frac{\alpha\,\delta\,(n+1)}{2\,(\beta\,\gamma-\alpha\,\delta)}\right)^2+\frac{\alpha\,\delta\,.\,n}{\beta\,\gamma-\alpha\,\delta}\right\}} \quad . \quad . \quad (3\text{A})$$

The sign of the radicle is always the same as that of $\beta\,\gamma-\alpha\,\delta$.

If it should happen that $\beta\,\gamma=\alpha\,\delta$ the above solution fails, but, returning to (2), we see that in this case

$$x=\frac{n-q\,p}{q+p+n+1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3\text{B})$$

so x is always unambiguously known.

Differentiating equation (2), we get—

$$d\,x=\frac{\frac{d\,n}{n-x}+\frac{d\,(\alpha\,\delta)}{\alpha\,\delta}-\frac{d\,(\beta\,\gamma)}{\beta\,\gamma}-\frac{d\,q}{q+x}-\frac{d\,p}{p+x}}{\frac{1}{q+x}+\frac{1}{p+x}+\frac{1}{1-x}+\frac{1}{n-x}} \quad . \quad . \quad . \quad . \quad (4)$$

If, now, α, β, γ, δ are the coefficients of activity of four bodies, A B, A D, C B, C D, and if the product $\alpha\,\delta$ for two conjugate bodies is much greater than that $\beta\,\gamma$ for the two opposite bodies, one finds realised a case of very great importance, applicable to the equilibrium of four bodies, acid, base, salt, and water. According to equation (2), if the quantities mixed of acid, base, and water are 1, n, and p equivalents, there are formed x equivalents of salt and water, where—

$$(p+x)\,x=\frac{\alpha\,\delta}{\beta\,\gamma}\,(1-x)\,(n-x) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

For strong acids and bases $\alpha\,\delta/\beta\,\gamma$ is a number of several millions, while x is, from the above, always less than 1 and n : hence to satisfy the equation it is necessary that $(1-x)\,(n-x)$ shall be very small (unless p is enormous) ; that is to say, that x must be almost equal to 1 (if n is greater than 1), or to n (if n is less than 1).

(24) *If one mixes a strong acid with a strong base, they unite for the most part to a salt, in such a way that there is formed a quantity of salt always a little less than that of the hydrate of which one has added the smallest equivalent portion.*

[This is rather an anti-climax.]

The clearest way to see this is to work some numerical examples. We have therefore made calculations on mixtures of a strong base (caustic soda) with a strong acid (nitric acid) on the one hand, and of a weak base (ammonia) with a feeble acid (boracic acid, supposed monobasic) on the other. The figures employed are taken from a previous section, with the supposition that the molecular conductivity of ammonic borate is equal to that of ammonic carbonate (an hypothesis which ought to be approximately correct). We have thus calculated that if one mixes 1 equivalent of acid with n equivalents of base in 100 equivalents of water, the amount of salt formed is given in the table below for several values of n.

Digitized by Google

1 *Nitric Acid and* n *Caustic Soda.*		1 *Boracic Acid and* n *Ammonia.*	
n	x	n	x
$\frac{1}{2}$	·4999981	$\frac{1}{2}$	·245
1	·998659	1	·404
2	·999993	2	·634
		3	·741

[The molecular conductivities used in this calculation are probably—

For HNO_3 ..... $\alpha = 3 \times 10^{-5}$ | For boracic acid ..... $\alpha = 4{\cdot}4 \times 10^{-9}$
For $NaHO$ ..... $\delta = 1{\cdot}5 \times 10^{-5}$ | For ammonia ..... $\delta = 8{\cdot}4 \times 10^{-8}$
For $NaNO_3$ ..... $\beta = 6 \times 10^{-6}$ | For ammonic borate. $\beta = 4 \times 10^{-6}$
For H_2O ..... $\gamma = 10^{-12}$ | For water ..... $\gamma = 10^{-12}$

so that $\frac{\alpha\,\delta}{\beta\,\gamma}$ in the first case equals 10^8, and in the second case equals 100, or thereabouts.]

What we have just said applies specially to the formation of salts of strong acid and base when the quantity of water is very considerable. From the above example (the formation of $NaNO_3$), as well as from proposition 24, we proceed to deduce the following observation, true for salts of strong acid and bases:—

(25) *The quantity of salt formed when one adds a strong base to a strong acid is sensibly proportioned to the quantity of base added, until the acid is saturated, after which the formation of salt sensibly ceases.*

An entirely different aspect is presented by the figures calculated for the formation of a salt from feeble constituents, such as borate of ammonium. In this case $\alpha\,\delta/\beta\,\gamma$ is not excessively great, so that for considerable quantities of water (p) it is not necessary for either $1-x$ or $n-x$ to nearly vanish. That is to say, although the acid is in excess the free portion of base is nevertheless sensible, and *vice versâ*. In this case we may apply equation (4), regarding all quantities contained in it except x and n as constant, and q (the original amount of salt) as zero. We thus find that—

$$\frac{dn}{dx} = 1 + (n-x)\left(\frac{1}{1-x} + \frac{1}{p+x} + \frac{1}{x}\right)$$

[which may be written more systematically, though less usefully for present purposes

$$\frac{dn}{dx} = \frac{n}{x} - \left[\frac{n-1}{x-1} + \frac{n+p}{x+p}\right].$$

Differentiating again we get*

$$\frac{d^2n}{dx^2} = \frac{2}{x}\,\frac{(p+1)(n-x)}{(p+x)(1-x)^2},$$

which is always positive, since x cannot be greater than n. This we can render into words thus:—

(26) *If one adds a feeble base to a feeble acid, or* vice versâ, *there is necessary for the formation of a given quantity of salt* (dx) *a quantity of base* (dn) *so much the greater as the formation of salt has proceeded further.*

Moreover, equation (4) shows that if n is greater than 1, the denominator is not very great, because $1-x$ differs sensibly from zero; so $\frac{dx}{dn}$ will have a sensible positive value even for $n > 1$, which means—

(27) *If one adds a feeble base to a feeble acid, or* vice versâ, *the formation of salt continues sensibly, even after the number of equivalents of the body added has surpassed that of the other body.*

The figures calculated for boracic acid and ammonia exhibit this property clearly. Between the two examples cited are a crowd of transitions which are realised by mixing a strong acid with a feeble base, or *vice versâ*. Everything depends on the magnitude of the factor $\alpha\,\delta/\beta\,\gamma$, and on p, the amount of water present. The laws deduced above have been long known by chemists. They are fundamental, and occur in most reactions—that is to say, in all reactions of electrolytes.

If in equation (5) the factor $\alpha\,\delta/\beta\,\gamma$ is a small number, as is probably the case for alcoholates,† the quantity of salt formed is almost zero. So if one mixes alcohol with any base, it only forms a very little alcoholate. But, according to law (23), final equilibrium only depends on relative quantities of the ions present, so if one adds water to an alcoholate it is destroyed, and turns into alcohol and hydrates. Here the *rôles* are changed; water is an acid stronger than alcohol, so it is necessary that water displaces most of the alcohol, as nitric acid displaces water from a hydrate, and this is in full agreement with fact. What is common to every case is the necessity of regarding water as an acid (or, if one likes it better, as a base), which concurs with other acids (or bases) in the equilibriums.

As, according to equation (4), $\frac{dx}{dq}$ is always negative, one perceives that the presence of salt (q) has always an opposing influence on its formation, the same as water behaves. However, the quantity of salt present in the reactions is generally small enough for this influence not to be noticeable.

(*To be continued.*)

* Dr. Arrhenius's mathematical expressions are sometimes unnecessarily long, so I rearrange them whenever convenient without compunction.

† According to all authors, alcohol is a conductor very inferior to water. On the other hand, the conductivity of an alcoholate is comparable to that of a hydrate. (See my work on the conductivity of alcoholic solutions.) [Author's note.]

LEGAL INTELLIGENCE.

Edison and Swan United Electric Company v. Shippey Bros.

This was an action heard before Mr. Justice Kekewich, in the Chancery Division of the High Court of Justice, on Friday last, to restrain the defendants, carrying on business in King-street, Cheapside, from selling a lamp made, as alleged, according to the patent of the plaintiffs (No. 4576 of 1879).

The Attorney-General (Sir R. Webster), Mr. Aston, Q.C., and Mr. Moulton, Q.C., appeared for the plaintiff company; Mr. Arthur Shippey conducted the defendant's case.

Mr. ASTON having opened the case for the plaintiffs,

Dr. Hopkinson, F.R.S., was called and examined, and gave an account of an inspection he had made, in common with Sir Frederick Bramwell and Dr. Fleming, of three lamps which were alleged to have been bought from the defendants. The first of these, he said, contained to all appearance a filament of carbon enclosed within a glass bulb through which the leading wires passed, the carbon filament being attached to the ends of the leading wires. There was an intimation on the glass bulb that the lamp was to be burned at a pressure of 50 volts. He tested the resistance of the lamp in a cold condition by means of a Wheatstone bridge, and found it to be 100 ohms. They afterwards placed the lamp in a photometer and applied an electric pressure of 50 volts to it, measuring the current passing through it and also the candle-power given out from it. The current was found to be ·84 of an ampere and the candle-power 3·61. At the higher temperature the resistance of the lamp was 59·5 ohms. They subsequently broke a small opening in the lamp under mercury, with the result that the mercury passed into the lamp and filled it with the exception of a minute space taken up by a gas bubble, proving that there was exhaustion to a very considerable extent, but that the vacuum was not perfect, although it might be so regarded for all practical purposes. A second lamp was broken up and examined by a microscope. Its diameter was found to be $\frac{1}{1000}$ of an inch, and from the appearance it presented he thought it had been flashed to a certain distance down. From the aspect of the filament, and also from the diminution of the resistance with the increase of temperature, he was almost certain that it was composed of carbon, and that it was, so far as he could make out, a carbon filament, such as that described in Edison's specification. Coming to the third lamp, he said it was to all intents and purposes of the same character as the other two. This is the substance of what was elicited during the first day of the trial.

On Saturday morning Mr. SHIPPEY made an application to be allowed to amend the pleadings, on the ground of the negligence of his solicitors to do so. He wished to amend in regard to the specification of Cheesborough, which was included in the alleged infringement. He argued that that specification was not valid, because Messrs. Sawyer and Man, of America, the inventors, were not parties to the disclaimers in the amended specification filed by J. Y. Johnson, to whom the patent had been assigned.

Mr. ASTON opposed the application, which he characterised as frivolous and untenable.

The learned JUDGE ruled that it would be to defeat justice to allow an amendment which raised an entirely different issue to that which appeared to be set up by the pleadings, and requested both parties to the action to confine themselves to the plain issue whether the defendants had infringed the plaintiffs' patents, which must for the purposes of the action be held good as they stood.

Mr. SHIPPEY then entered upon the cross-examination of Dr. Hopkinson with respect to the comparative extent to which the lamps tested might represent a vacuum, eliciting from the witness that the volume of the bubble left when the mercury entered the globe was as near as he could tell 236 cubic millimetres. The bubble might have been of air, or of some other gas. The vacuum was not very perfect, but was tolerably good for the practical purposes of a lamp. He said that Edison, in his specification, mentioned the millionth part of an atmosphere as an illustration of the degree of vacuum which could be obtained, and the defendants, no doubt, did not succeed in reaching so high a vacuum as Edison had indicated. He was not prepared to say whether Edison made all his lamps with a vacuum of a millionth part of an atmosphere. If the filament contained tetra-chloride of platinum, or was saturated with a metallic substance, he did not think that that would account for the bubble in the globe. If the filament were substantially carbon, that, in his opinion, would be a carbon filament within the meaning of Edison's specification, even though it was coated with platinum. Mr. Shippey asked whether, supposing that the peculiar filament witness tested was coated with a solution of tetra-chloride of platinum, and supposing it was then re-coated with silicon glaze, and it was afterwards re-coated with platinum, the filament being subsequently carbonised, from his experience he would consider that a filament within the terms of Edison's specification. Dr. Hopkinson replied that, supposing all that, of which he detected no evidence whatever, to have been the case, then he would say that it would depend broadly upon the thickness of those coatings whether the filament was broadly and substantially carbon or not. Mr. Shippey asked whether that would not be a semi-metallic substance, to which witness replied that the coating no doubt would be metallic. The body of the filament would be a pure carbon. Mr. Shippey handed a filament manufactured by his firm to witness, asking him if he could tie a knot on it, to which he replied in the affirmative. Mr. Shippey next asked whether that could be done with a lamp-black and tar filament. Witness said it could not, perhaps; but he had no doubt it could if there was a thread in it as described by Edison. Taken generally, the filament was distinctly an Edison filament. At the conclusion of his cross-examination of witness Mr. Shippey stated that the lamps which had been put in, and upon which evidence would be given, were not manufactured in accordance with his specification, although he sold them.

Digitized by Google

Charles Henry Gover was next called, and admitted having purchased a number of lamps from the defendants. In cross-examination he admitted also that, when the lamps were supplied to him, Mr. Shippey said that as witness asked for high-resistance lamps they would be supplied, but that the firm did not manufacture high-resistance lamps. The lamps put in by Dr. Hopkinson having been identified as those purchased from the defendants, the Court rose.

On Tuesday Mr. D. H. Bowie and Dr. Fleming were called and examined and cross-examined. Mr. SHIPPEY then said that he felt himself unable, owing to legal technicalities in the case, to properly deal with it. He was willing to submit to a judgment upon terms if the other side would agree. There was an action pending by the Anglo-American Brush Company which he had no doubt would be fought upon the true merits of the incandescent lamp for the first time. It was useless for him to proceed with the case. He would consent to an injunction if execution were ordered to be stayed until the Brush Company's action had been disposed of and every lamp accounted for. He assured the Court that he had amongst his stock four different classes of lamps which did not come within the definition of carbon filament lamps, but as he was labouring under the disadvantage of not being represented by counsel he made this offer to the plaintiffs. He had another action pending for intimidation, with which he would not proceed until the other case which he had referred to was heard.

Mr. ASTON agreed to a stay of execution for a month.

His LORDSHIP said he would simply treat the action as an undefended one. The evidence in favour of the plaintiffs so far was conclusive, and none being adduced by the other side, he had nothing to do but find a verdict for the plaintiffs, who were entitled to either an account or damages, but not both.

Mr. ASTON said that the plaintiffs would elect to take damages.

COMPANIES' MEETINGS & REPORTS.

The Direct United States Cable Company (Limited).

The twentieth ordinary general meeting of this Company was held on Friday, the 29th July, 1887, at Winchester House, 50, Old Broad-street, Mr. John Pender presiding.

The ACTING-SECRETARY (Mr. T. Finnis) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the report is in your hands; I presume you will take it as read. I shall give you, as usual, a few details connected with the past six months' working, with some other general remarks. The revenue for the half-year to 30th June, after deducting cut-payments, amounted to £23,572; and the working and other expenses, including income-tax (but exclusive of cost of repairs) absorb £15,905, leaving a balance of £7,667 as the net profit of the half-year, making, with £229 brought forward from the previous half-year, and £4,246 transferred from the reserve fund account, a total of £12,142, which has been appropriated to the payment of the undermentioned dividends:—Interim dividend of 2s. per share for quarter ended 31st December, £6,071; interim dividend of 2s. per share for quarter ended 31st March, £6,071—total, £12,142. A final dividend of 2s. per share is now proposed for the quarter ended 30th June, the funds for which will be provided out of the interest on the reserve investments. This final dividend, with the three interim dividends already paid, will make up a total of 2 per cent. for our financial year. The revenue at the 6d. rate shows a reduction of £4,873 when compared with the corresponding period of last year, owing to the 1s. 8d. tariff having been in force for the first four months of 1886. This reduction in the receipts would have been much greater but for a large increase in the volume of traffic carried at the 6d. rate. The expenses in London show a reduction in salaries, printing and stationery, and stamps. The increase shown in the rent and office expenses is owing to the removal of the offices, which was notified to the meeting held in January last. The remaining items are about the same in amount as in the corresponding period of last year. The expenditure at the stations shows an increase, on the whole, of £580, owing entirely to the failure of the French Company to perform their engagements. Had these been carried out, a reduction in nearly every item would have resulted. These amounts, however, are all subject to adjustment on settlement with the French Company. On the whole, the total expenses and other payments (repairs excepted), are only £38 in excess of the corresponding period of 1886. The interruptions in the cables during the past half have been three in number—two breaks of the short section and one of the main section having occurred. The repairs were in each case effected with the least possible delay, and at a total cost, including cable, of £5,223, which, as stated in the report, has been charged to the reserve fund, as usual. Up to the present, £4,246 only has been required and applied out of the interest on the investments, towards payment of dividends. The reserve fund account, after providing the above amounts, and being credited with interest on the investments, and profit on sales of securities, now stands at £325,420. The investments, which appear in the balance-sheet at cost price, are worth very much more to-day (about £13,000) than their cost to the Company. Gentlemen, I have given you these hard facts, and now it is my duty to make a few remarks upon the present position of the Company. You are all aware that the 6d. rate still continues. It has been going on for fifteen months now, and I am glad to say that during those fifteen months there has been shown a very wonderful development of traffic. I am not going to tell you that that 6d. rate is eventually to be the permanent rate, because personally I do not believe that 6d. will ever pay even if all our present cables were working to the full extent. But I am quite prepared to say this, that there is a very general opinion not only amongst our shareholders, but amongst the public generally, that the 6d. rate ought to be continued until we are perfectly satisfied of the extent of its development, and how far it would answer our purpose in the future to adopt it before we come to agree upon a rate which would be fair to the shareholders and equally fair to the telegraphing public. I think that that is a policy which is a sound policy, and I hope our shareholders will support us in it. Now, gentlemen, I think it is very right and proper that there should be the most perfect confidence existing between the shareholders and the Directors. We have no secrets. We let you know everything that you are entitled to know, or everything that would be of interest to the Company to know. You see paragraphs in the newspapers every day about negotiations going on here and there as to the settlement of this question. I may tell you that there are no negotiations whatever going on in England. Mr. Mackay arrived in England the other day and, I believe, returned to America. I do not believe that any gentleman officially connected with these companies has had any interview or any exchange of opinion with Mr. Mackay. The settlement of this question, I believe, is to be made on the other side of the Atlantic, and I will give you the reasons for my views. I believe Mr. Mackay, before he left America (about a fortnight or three weeks ago), had an interview with the Western Union Directors. I believe it was arranged then that some committee should be appointed to go into this question. So far we have heard nothing, we know nothing, of what has been done; but we know this, that it is in the hands of men whose interests are very vast indeed. It just occurred to me this morning that I may tell you something of the stake that those gentlemen on the other side hold to show you that their interests are so great that, if they made a good bargain for themselves, they could not make a bad bargain for us, as we must be partners in any bargain or agreement they may come to. Now, gentlemen, I find that the capital of the Western Union—the great land system of America—is about £17,400,000. That is an enormous sum of money. The Baltimore and Ohio Company and the other land line companies' capital is said to amount to £6,000,000. The cables belonging to the American Cable Company, which are leased by the Western Union Company, represent £2,800,000, on which the Western Union have guaranteed 5 per cent. That is a pretty big business of itself. The capital of the Mackay-Bennett Company is something like £1,500,000, making up altogether very nearly £28,000,000 sterling. That is the cost of the system on the other side; therefore, you can well understand that gentlemen with interests so largely in excess of our interests are not likely to make a bad bargain for us. The Western Union during the last two or three half years have paid no dividend. Four years ago they were paying 7 per cent, which went down to 6, down to 5, and so on; and you can well understand that it is to their interest to make a good bargain, and to come to the end of this competition at as early a date as possible. Therefore, I think, gentlemen, that we are right in leaving the whole of the negotiations in their hands. They can come to no decision without consulting us, and we shall come to no decision without being satisfied that your interests are fairly and well protected. With these few remarks, I beg to move—

"That the Report of the Directors, dated 8th July, 1887, together with the statement of accounts to 30th June, 1887, annexed thereto, be and the same are hereby received and adopted; and that a final dividend be now declared of 2s. per share free of income tax, making, with the interim dividends already paid, a total dividend of 2 per cent. for the year ending 30th June, 1887."

Mr. WILLIAM FORD seconded the motion.

Mr. GUESDON animadverted on the general apathy shown by shareholders as to the property in which they locked up their money, maintaining that not one out of fifty knew the conditions under which that property was ruled. It was, therefore, their duty to make themselves acquainted with the Articles of Association and all agreements that the Company might make. He was promised a look at the agreement with the Anglo-American Company, but he had never had time to go to the office. There was another matter he might mention. He did not know whether any imputation might be cast upon him, which he gathered might be the case, in consequence of having received a letter on the subject, in which it was supposed that, owing to the remarks he had made at a meeting, he favoured the Commercial Company. He knew as much about the Commercial Company as the inhabitants of Kamtchatka.

The CHAIRMAN: Who imputed to you anything of the kind?

Mr. GUESDON said that it was no one in the Direct Company. In the report which was made some time ago it was stated that the greatest economy had been exercised in working the Company. In answer to that he would remind them that the expenses of working in London in 1883 amounted to £2,742, whereas in 1887 they were £3,307.

The CHAIRMAN: You are comparing a period when the rate was 2s. with a period when the rate is 6d.; and it so happens that if you double your traffic you must also increase the expense of working it; but, on the whole, as may be gathered from the statement I have made to-day, we have expended only £38 more this half-year than in the corresponding period of last year.

Mr. GUESDON wished to point out that the Chairman had said that all sorts of propositions had been made to avert the difficulties under which they now suffered, but had never ventured to say what those propositions were, and how it was that the present state of affairs was forced upon them.

The CHAIRMAN: You are now stating what is not strictly correct. I have stated the reasons from time to time at meetings, and we had the entire approval of the shareholders for going down to the 6d rate. I stated from time to time that if the Commercial Company had adopted 2s., there never would have been any movement at all, and that we could trust to time to make up what traffic they might take away from us. We were forced in self-defence, and with the entire approval of the shareholders of the Direct Company, to go down to a 6d. rate. Up to that time this Company paid 5 per cent. to their shareholders steadily for years. The

Digitized by Google

rate was 2s., and during those years we put by a reserve fund which has made this one of the strongest of the telegraph companies at the present time. I am referring to what you said at the beginning of your speech to-day. You said that shareholders should get hold of the Articles of Association and look into their affairs; but you wound up that by saying, "I have not had time myself to go to the office." You are asking people to do what you have not done yourself; and if you are going to come here and represent the shareholders you should first make yourself thoroughly acquainted with the grievances and the faults that they find with the Board, and then I shall listen to you with the greatest possible pleasure, but when I find you speaking without the book and departing from facts I have a right to protest. I want the shareholders to understand this, that if Mr. Guesdon desires to come here to represent and speak for the shareholders, I ask Mr. Guesdon to come to the office, where we will give him every possible information he can wish to make up a complete and careful statement. He can then make his statement, and you will be able to judge betwixt him and the Board. If he will only do that I shall value Mr. Guesdon's suggestions, but if he goes on to make loose statements, which I and my colleagues must contradict, I think I am entitled to the support of the meeting in protesting.

Mr. GUESDON proceeded to say that when the Chairman got up and spoke of exercising economy, and so forth, he could not reconcile it with the fact that the Directors' fees were £1,500. It was peculiarly disappointing in the circumstances in which the Company was placed to find that the shareholders should receive a dividend of 2s., to be taken out of the reserve fund, and that the Directors should show them no sympathy at all. What was the value of the property, and what was a fair and reasonable compensation for the outlay? That was the important consideration. It did not matter whether an article cost £500. When changes reduced its value to £200 they must be satisfied to deal with it in that sense.

Mr. WEATHERBY had hoped that the hon. proprietor would have concluded his speech by moving an amendment. As that had not been the case he (the speaker) rose for the purpose of doing so. When the question of directors' remuneration was referred to they heard continually that it was necessary to have gentlemen of experience and gentlemen who could protect their interests on the Board. Two per cent. was not an evidence of skill on the part of the Directors. £1,500 every half-year was a very nice income for gentlemen sitting on the other side of the Board. They were told that their present unfortunate state of affairs was in consequence of competition. But there would always be competition in business, and the duty of business men was to endeavour to meet that competition. They ought either to make some arrangement with the Commercial Company, or do something else to meet the difficulty. He quite appreciated the remarks of the previous speaker; and he would conclude by moving, as an amendment, "That the report be not accepted unless the Directors agree that their remuneration shall be struck out of the accounts."

Mr. GUESDON seconded the amendment.

Mr. JOHN NEWTON said he could not sympathise with the amendment just made, though he did sympathise with the feelings of the gentleman who moved it. He considered, however, that the Directors were doing such good, arduous work in the contest that was going on—work which he considered was of vast importance to the welfare of the Company—that the question of the Directors' fees should be in abeyance until they saw what the result of their policy might be. When matters were settled between the competing companies, and they had arrived at a state of peace, if they did not get a very much better dividend, he would strongly urge that the shareholders should take the subject of the Directors' remuneration into their own hands if the Directors themselves did not voluntarily reduce the amount. There was no doubt that this was a burning question, and he had for a long time directed attention to it. He wished, at the same time, to congratulate the chairman on the bold step he continued to take in trenching on the reserve fund to go on paying a dividend. The value of the property as against other Atlantic cables would be greatly strengthened by a continuance of that policy. The principle of some companies in putting away a reserve fund which could not be drawn upon in such a case as theirs was perfectly absurd. If there was one thing that he liked more than another it was to hear shareholders combat directors on a question of accounts, because whatever errors the shareholders might make in so doing it had a tendency to make the Board economise in administration. Nothing could be more satisfactory than the Chairman's statement as to the enormous interests in telegraph cables held on the other side of the Atlantic. He could not help thinking that it was the jealousy of England that had damaged their property.

Mr. JACKSON rose, not so much to find fault as to congratulate the shareholders and the Board on certain circumstances which he would like to mention. Like his friend, Mr. Newton, he could not support the amendment in reference to the reduction of the Directors' fees, because the question was settled at a previous meeting, and he thought it would be highly injudicious to do anything of the kind. He congratulated the meeting on the elimination from the report of what he used to be distressed to hear. He was distressed to hear that the reduction in receipts was attributable to competition. Competition, as had already been explained, was one of the conditions of trade, especially in a country that professed free trade, and to attempt to attribute their losses to such a cause was an absurdity—an anachronism. The tariffs were chosen and enforced by the "pools," and they accepted the conditions and were willing to wait the result. Now, at the present time, after fifteen months' experience of the 6d. rate there was sufficient evidence to satisfy the united Boards on this side that they should put an end to the present state of things. There was the fact that they were paying a very small dividend, a portion of which came out of the interest of the reserve fund. He thought they ought to fix upon a 1s. rate. He took exception to some portion of Mr. Guesdon's remarks. He thought it was very unfair to speak of the extravagance of the management of the Company. There was no comparison as between the Direct and the Anglo-American in that respect. Many of the servants of the Company were living on very low wages, and a cheeseparing policy, with poorly-paid clerks, would be a very false one.

The CHAIRMAN: I have listened to the four speakers with mingled feelings. Two of them have had very considerable experience—I refer to Mr. Jackson and Mr. Newton—who have followed the fortunes of the Company from the beginning. The other gentlemen have not, I believe, had the same experience in telegraph affairs, but I am always prepared to take an idea, let it come from what source it may. But I assure you, gentlemen, if we were to conduct the affairs of the Company according to the four different opinions put before us to-day, we should be in the greatest possible difficulty at the end of a month. Our policy is a consistent policy. We have put it before you from time to time; and if Mr. Jackson, who has spoken so eloquently to-day, will carefully consider the remarks I have made, he will find that what we are endeavouring to do is to arrive at a figure which will yield a fair return to the shareholders, and also be fair and just to the telegraphing public. The telegraph is established, not to benefit the public so much as the people who put their money into it. The public are indebted to the shareholders of the Company, and it is our duty to protect the shareholders as far as we possibly can. I said from the first, and I do not believe now, that the sixpenny tariff will ever pay; but these are all matters that must be discussed calmly, with a view to a peaceable settlement. We are fighting the sixpenny battle now to bring about that settlement. When this question is settled, if it is not done satisfactorily, then I say, in answer to Mr. Jackson and Mr. Newton, then come forward and demand from us an explanation or our resignation. That is my view as Chairman and as a Director of this Company. I need not go into many details, for I think it is unnecessary. I believe the settlement of this question is within a moderate space of time. I have asked you to be patient, because I believe the subject is in the hands of men who will bring it to a satisfactory issue. It is an absolute necessity for the interests of all concerned that its settlement should not be prolonged. You have had confidence in us a very long time. We came into this Company after four years of its existence. Not a shilling had been paid in dividends. We have cleared off £100,000 debentures, which was a burden on the shoulders of the shareholders at the time. We have paid you all through 5 per cent., and at the present moment, we stand with a reserve fund of £325,000. That was not done, Mr. Guesdon, surely, by incompetent men. If there had been the same class of men on the Board when we joined, that would not have been your present position. It was the management of experienced men, and men of ability, and, I am bound to say, of character and reputation that has placed this Company in its present condition. Even the gentlemen who lead the opposition to the Anglo-American Company complimented the Direct Company upon their sympathy with the shareholders. We have done our duty, gentlemen, and are doing it; and I would say to Mr. Newton, if there is any agreement or Articles of Association that you would like to see, come to the office, and we shall lay them before you. They are now in the archives of the Company, and are at your service at any time, but it is not our business to come here and read over the Articles of Association and agreements of the Company. Time is too valuable for that. We have a well-defined policy; we follow that policy, and we believe it to be for the benefit of the shareholders, and I would say, in conclusion, to the body of shareholders, "Leave well alone."

Mr. WEATHERBY felt that there was a want of courtesy in the remark made by the Chairman as to his (the speaker's) want of experience in this kind of business. He had unfortunately too much experience in it, being a shareholder in the Anglo-American and the Direct as well. He still maintained the justice of his remarks, although he would withdraw his amendment, because he was quite sure it would not be carried. Would the Chairman kindly give his own opinion as to what he considered a fair time to wait for a settlement?

The CHAIRMAN replied that the position he occupied in relation to other companies would not warrant his making any remarks that would tie their hands in any way whatever. While he had made the remark about Mr. Weatherby's inexperience in regard to telegraphy, he had not the slightest desire to reflect upon that gentleman's general experience and knowledge.

The motion was then put and carried.

Mr. UNDERDOWN, Q.C., moved—"That Mr. John Pender be and he is hereby re-elected a Director of this Company," and said that he was quite sure that if Mr. Guesdon would go in for reducing the number of Directors that gentleman would not like to see it diminished to the exclusion of their excellent Chairman. He was glad to see that Mr. Pender occupied such a prominent position at the dinner to commemorate the fiftieth anniversary of the electric telegraph, where the highest electrical authority, Sir William Thomson, said that it was to Mr. Pender and Mr. Cyrus Field that was due the honour of commencing Atlantic telegraphy.

Mr. FORD seconded the motion, which was cordially agreed to.

The CHAIRMAN next moved—"That Mr. Emanuel Maguire Underdown be and he is hereby re-elected a Director of this Company," and referred to the excellent service that gentleman had rendered to the Company through his great legal knowledge, and more particularly in dealing with the French Company, because of his perfect command of the French language.

The Lord HAWKE seconded the motion, and it was carried unanimously.

Mr. JACKSON next proposed the re-appointment of the Company's auditors (Messrs. J. G. Griffiths and J. Sawyer) for the ensuing year at a remuneration of £50 each, eulogising the painstaking manner in which those gentlemen performed their duties.

Digitized by Google

Mr. NEWTON seconded the motion, and it was carried *nem. con.*

Mr. SHELDON proposed, and Mr. NEWTON seconded, a vote of thanks to the Chairman and Directors, which was cordially passed.

The CHAIRMAN: Gentlemen, I must in the first place thank you for the honour you have done me in re-electing me a Director, and in the second place to thank you on behalf of my colleagues for the compliment you have paid us by this vote of your renewed confidence. There is an old saying among the Italians that it is always pleasant to go away with a sweet taste in one's mouth, and I want you to carry that sweet taste away to this extent—that you may rest assured that the Directors have a great sympathy with the shareholders at the present time. The dividend we have paid you to-day is, I must confess, a miserable one, but we are only partners, and small partners, in a large concern, and consequently we are obliged to be guided more or less by our more powerful allies; but I think I have stated clearly to you to-day that it is to the interest of those allies to settle this question as soon as possible, when we shall be in a position to declare a higher dividend.

The proceedings then terminated.

The Edison and Swan United Electric Light Company (Limited).

Report of the Directors, to be presented to the shareholders at the fourth annual meeting to be held at the Cannon-street Hotel, on Tuesday, 9th August, at 12 o'clock.

The sale of lamps and the business of the Company has progressed in a satisfactory manner during the year, and has resulted in a profit of £16,221. 17s. 8d., which sum the Directors will propose to apply to the extinction of the amount standing to the debit of profit and loss. During the year the Directors have paid off the mortgage of £3,000 on the Benwell, and a like amount on the Green-street property. They are trying to find purchasers for these freeholds. Installation work has been more active during the past twelve months, and the Company has lighted, amongst other places, the Athenæum and National Liberal Clubs, the National Provincial Bank, the house of H.R.H. the Duc d'Aumale, various ships, and private houses in town and in the country. The Directors in their last report informed the shareholders that Messrs. Woodhouse and Rawson had given notice of appeal against the judgment of Mr. Justice Butt in both the actions for infringement of the Company's patents which he had decided against them. The appeal in the first action was heard before Lord Justices Cotton, Bowen and Fry, who upheld the judgment of the Court below. The appeal in the second action was heard before Lord Justices Cotton, Lindley, and Lopes, who also upheld the judgment of Mr. Justice Butt. Messrs. Woodhouse and Rawson were condemned in costs in both actions, in respect of which costs they have as yet made no payment. Other actions are pending in connection with the Company's patents, but in these the Directors are advised that there is no probability of the judgments of the Courts of Appeal being reversed. The shareholders may rest assured that the Directors will do all in their power to maintain the valuable patent rights which the Company possesses. The electric lighting industry, in spite of the difficulties created by the Electric Lighting Act, is progressing, although the rate of progress in the United Kingdom is slow compared with that in the United States and in some parts of the Continent, and the business generally is becoming sounder than it was, although much cheap bad installation work is still being done. The Directors are preparing to meet any increased demand which may arise for lamps in the coming winter. Mr. Shelford Bidwell, F.R.S., retires from the Board, and offers himself for re-election as Director. Messrs. Quilter, Welton and Co., the auditors, also retire, and offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 15th, 22nd, and 29th July amounted to £2,870, £2,763, and £2,500 respectively.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of July was 3,277, estimated to produce £2,600, against 3,412 messages, producing £2,818 in the corresponding month of last year. The traffic receipts for the month of April, estimated to produce £2,900, realised £2,964.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of July amounted to £1,532, against £1,280 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July amounted to £45,805, and to £43,708 in the corresponding period of 1886.

EASTERN EXTENSION AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July amounted to £38,520, and to £34,931 in the corresponding period of 1886. Increase £3 589.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending 30th July amounted to £4,6:0.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the three weeks ending July 15, 22, and 29, were £2,267, £1,771, and £2,092 respectively, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 31st July are £2,431, as compared with £2,414 in the corresponding period of 1886. The April receipts, estimated at £5,566, realised £5,400.

WOODHOUSE & RAWSON (LIMITED).—The application list of this new company's shares will be closed on Monday next for London, and on Tuesday, at 12 o'clock, for the country. We hear that the shares are already over applied for, and business has been done at ½ to ¾ premium.

NEW COMPANIES REGISTERED.

UNITED TELEPHONE COMPANY OF ROSARIO (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, with a capital of £20,000 in shares of £10 each. Object: To purchase and take over the undertaking known as "Compania Telefanos Unidos del Rosario" (now established in Rosario in the Argentine Republic), upon the terms of a draft agreement already prepared and made between the River Plate Trust, Loan, and Agency Company (Limited), of the one part, and the United Telephone Company of Rosario (Limited) of the other part, subject to any modification the directors may approve, to carry on the businesses of telephone and telegraph companies in the Argentine Republic. The first directors shall be appointed by the subscribers to the Memorandum of Association; qualification, the holding of at least £200 in the capital of the company; remuneration to be fixed in general meeting.

NOTES.

KARLSBAD.—A concession has been obtained for the construction of an electric tramway in this town.

PARIS THEATRE LIGHTING.—The electric light is now being installed in the Théatre de la Rennaissance, the Théatre de l'Ambigu, and the Théatre des Menus-Plaisirs.

THE AMERICAN NATIONAL TELEPHONE ASSOCIATION.—The American National Telephone Association has decided to hold its meeting at Pittsburgh, commencing September 26th.

GENOA.—The Ganz Company of Buda-Pesth is negotiating for the establishment of a central lighting station on a very large scale at Genoa. Zipernowski-Déri transformers will be used.

ST. PETERSBURG.—An exhibition of the mineral oil industry and other lighting materials will be opened at St. Petersburg in November next. There will be a section for electric lighting.

LARDEN'S "ELECTRICITY."—We have received from Longmans, Green and Co. a copy of "Electricity for Public Schools and Colleges," by W. Larden, M.A., author of "A School Course in Heat."

ELECTRIC RAILWAYS FOR INDIA.—Our contemporary, the *Indian Engineer*, referring to the progress of electric railways, remarks that in India there is "not only a large but a very promising field" for this application of electricity.

PARIS.—One of the iron conduits employed in conveying compressed air for supplying motive power to some dynamos in the Faubourg du Temple burst open on Monday last and caused very considerable damage, besides wounding three people.

MALTON.—The Malton Local Board has received an "informal" offer from an electric lighting company to undertake the lighting of the district for £1,500 per annum. The present cost of gas lighting is £580, so that this is, no doubt, a genuine offer.

LUCCA.—A small installation of Zipernowski-Déri transformers has been put up at Lucca, and is used both for public and private lighting, although there are only 200 lamps in all. Power is obtained from the River Lima at a distance of three miles from the town.

THE ATLANTIC CABLE RATES.—A New York telegram in the *Standard* states that the Commercial Cable Company has announced that it will in a fortnight reduce its rate to 12 cents per word, unless meanwhile other companies agree to advance the charge to 40 cents.

POST OFFICE TELEGRAPH CLERKS.—From the annual report of the Civil Service Commissioners we learn that during the last twelve months there have been 1,177 male competitors for 220 vacancies on the telegraph staff, and 836 female competitors for 80 vacancies.

LIGHTHOUSE COMMUNICATION BY TELEGRAPH.—According to the *Daily Telegraph*, Sir E. Watkin has agreed to take charge of a Bill in the House of Commons during the present Session to enable Lloyd's to connect (at their own expense) the lighthouse on Tory Island with the mainland of Ireland by sudmarine cables and land wires, and to establish telegraph stations.

EARLY USE OF THE MAGNET IN SURGERY.—In the *Phil. Mag.* for August, 1808, there is an interesting account of a successful operation performed by the aid of a magnet, in which a small piece of iron, which had *embedded* itself in the eye of a blacksmith, was extracted after resisting the efforts of the surgeons for no less than five months. So far as we are aware, this is the earliest record of the use of the magnet in surgery.

TELEGRAPH LINES IN THE EAST.—The Netherlands Indian Government will, it is said, make provision for stretching a telegraph line across Sumatra from west to east to continue the existing lines to Deli. There is some talk also of laying a cable from Situboudo, in Java, to Macassar, in Celebes, *viâ* Bali Buleling. Borneo and other principal islands in the Netherlands Indian Colonies are at present cut off from all telegraphic communication.

NIAGARA.—It is stated that the Buffalo Electric Light Company has entered into a contract with the Niagara Falls Hydraulic Tunnel and Power Company to take 10,000 horse-power, at 15 dollars per horse-power per annum, for lighting the city and manufacturing purposes. The route for the proposed cable has been surveyed from Niagara Falls, a distance of 20 miles. Negotiations are also pending for lighting and supplying power to other towns in the vicinity.

BERLIN.—The following are the latest statistics showing the position of the telephone service in Berlin :—Number of subscribers, 6,000 ; length of wire, 12,000 kilometres ; conversations per diem, 100,000 ; inter-urban communications, 1,500 to 2,000 per day. From these figures it appears that in proportion to population the telephone is nearly five times as much in use in Berlin as in London ; the number of communications per instrument per day is also very high.

OMNIBUS LIGHTING.—The General Omnibus Company are following the example of their competitors, the Road Car Company, in making trials of electric light in their vehicles. The Omnibus Company has, however, adopted an accumulator service. This will, we fear, prove a severe blow for the Eclipse Primary Battery people, who, judging from their financial proceedings, must have anticipated that nothing but the Eclipse Battery would ever be used for the purpose in all the omnibuses and tramcars of the kingdom.

ELECTRIC LIGHTING IN SCANDINAVIA.—Electric lighting was recently introduced at the Central Railway Station, Christiana, very successfully, involving a loss to the gas works of £2,000 a year. In Christiana the gasworks are city property, and the Corporation is now going in for an electric light plant of its own. The steamers running along the West Coast of Norway have been fitted up with Edison installations. In Stockholm the leading theatre is now lighted by electricity, and the city of Gothenberg, Sweden, is to have its streets lit by electricity.

CHICAGO.—At Chicago an extensive scheme for lighting the whole of the bridges and viaducts of the river has been adopted, and will at once be carried out. One hundred arc lights will be required, and the circuit will be ten miles in length. The specification states that the cables, after being led to the river-side by an underground channel, are to be dropped into the river, and suspended below the frost line in such a way as to be readily removed, when required, for dredging or other purposes. The cables are to be iron armoured, and the insulation is to be not less than 500 megohms—per mile presumably.

ELECTRIC TRACTION AT PHILADELPHIA.—Mr. Reckenzaun (upon whom, by the way, our American cousins have bestowed the distinguished title of "Professor") has recently been assisting at some trial runs of an electric tramcar in Philadelphia. Storage cells are used to supply current to a Sprague motor,

Digitized by Google

and very successful results have been attained. It is unnecessary to add that Mr. Reckenzaun's long continued study and extensive practical experience in all matters appertaining to electric traction and the working of secondary batteries should render his services of the greatest value to the American electricians, who are only just commencing to launch out in this particular direction.

BRAZIL.—The Zipernowski-Déri transformers have made their way into Brazil, and an installation of 1,000 lamps is in process of construction at San-Paulo. The Ganz Company has supplied the engines, of 150 horse-power, and also the arc lamps. Edison lamps of 16 candle-power have been supplied by the Compagnie Continentale of Paris. Overhead conductors of bare copper are used. The installation has been carried out by the firm of Marques, Montte and Co., who have acquired the exclusive rights for the Zipernowski-Déri system in Brazil. A paper published in Rio de Janeiro states that a new incandescent lamp, invented in Brazil, has recently been exhibited in that city, and, in the opinion of the local experts, is superior to either Edison or Swan.

THE CARDEW VOLTMETER.—Messrs. Paterson and Cooper write us as follows:—"In describing the above in your issue of last week there occurs an error which we should like to correct. The instrument is said to read to 360 volts, a mistake doubtless arising from the fact that the one inspected by you had not been calibrated. When the calibration is completed there is marked on the dial, in addition to the scale of 360° in black, a direct scale of volts in red, one end of the pointer painted black showing the deflection in degrees, the other painted red giving the volts producing it. The instrument described is calibrated to 120 volts, the deflection produced by this difference of potential being 360°. We are at fault in not pointing this out when we sent you the voltmeter."

BEANFEAST TO THE EMPLOYÉS OF THE ELECTRICAL POWER STORAGE COMPANY.—The annual dinner to the *employés* of this company took place in the Banqueting Hall, at the Royal Pavilion, Brighton, on the 30th July. The dinner was served at 12:30, the chair being taken by Mr. J. Irving Courtney, managing director, and the vice-chair by Mr. E. Clark, foreman of the works, in the unavoidable absence of Mr. W. H. Patchell, works manager. The chairman proposed the loyal toasts, the vice-chairman "The Company and Directors." After these toasts had been duly honoured, the chairman referred to the extensive application at home and abroad of the E. P. S. accumulators, and especially to the rapid increase in the demand for storage batteries in America. After several songs and speeches, the company dispersed for the beach, and met again at the railway station at 8:40 for the return journey to London. This makes the fifth annual dinner.

MORE ACCIDENTS FROM GAS IN THEATRES.—Some of our Continental contemporaries make it a practice week by week to record all the cases of fires or explosions due to coal gas which come under their notice, and it is but seldom that their columns are devoid of such catastrophes. We have not hitherto thought it desirable to follow this practice; but in view of the recent disclosures in the *Saturday Review* as to the condition of the London theatres, it is certainly the duty of every one concerned to endeavour to bring home to the authorities the very real character of the danger which exists in every public building of this character lit by gas light. At Toulouse a concert hall has just been almost entirely destroyed by fire. The outbreak occurred at two o'clock in the morning, and was due to the escape of gas. At the theatre at Nîmes, on Monday last, during a distribution of prizes to the pupils of the conservatoire, an explosion of gas took place in the basement, seriously wounding an attendant, and causing a panic which might have had the gravest consequences.

THE BRITISH ASSOCIATION.—A meeting of the Newcastle-on-Tyne Literary and Philosophical Society was held on Wednesday to consider the advisability of inviting the British Association to Newcastle in 1889. The Mayor of Newcastle (Sir B. C. Browne) occupied the chair, and among those present were representatives of the different educational and scientific institutions and the Mayor of Gateshead and Tynemouth. Lord Armstrong wrote approving the project for which the meeting had been called, and offering a contribution of £200 towards the expenses. Sir Lowthian Bell and others also wrote in favour of inviting the British Association. Dr. Hodgkin moved that the Mayor be requested to invite the British Association to Newcastle in 1889, which was seconded by Dr. Brady, of Sunderland, and supported by the Sheriff of Newcastle and carried. The following were appointed a committee in connection with the proposal:—Lord Armstrong, Lord Ravensworth, Sir Charles Mark Palmer, M.P., Sir Lowthian Bell, the Mayor of Newcastle (Sir Benjamin Browne), Mr. Hodgkin, Prof. Merivale, Mr. W. D. Stephens, Mr. N. H. Martin, Mr. Dunn, Mr. Emley and Mr. J. J. Butcher.

THE FIRE AT WHITELEY'S.—We notice that Mr. Whiteley is reported to have remarked to an interviewer that he had already adopted every possible precaution against an outbreak of fire which the ingenuity of his architect could suggest. We may, however, be permitted to observe that one precaution had been omitted. Mr. Whiteley's premises have hitherto been only partially lighted by electricity, and the descriptions of the recent fire were unanimous in attributing the rapid extension of the flames to the ignition of gas from the broken pipes. On this question the *Daily News* writes as follows:—"The fire at Whiteley's gives to electricity an opportunity of turning the tables upon gas. When first electric lighting came into vogue, there were many alarms as to the risks of fire through overheating of the wires. These had to be allayed by soothing assurances as to the character of the currents, by careful insulation arrangements, and by the invention of fusible plugs to break the current in case of the slightest danger. In Saturday's fire gas seems to have played an important part. A correspondent writes to us to point out that the vast system of gas-pipes in the burning premises aggravated the difficulties of the firemen, and probably prevented the restriction of the fire to its original limits. 'If,' he adds, 'the entire buildings had been lighted by electricity, much of the danger might have been averted.'"

FAILURE OF THE AMERICAN CARBON COMBINATION.—The attempt to maintain "a ring" amongst the American carbon makers has utterly broken down. Previous to the combination the selling price of carbons had been forced down to $10 or $12 per thousand. The prices fixed by the "ring" were from $20 to $25 per thousand, with the immediate effect, as our readers have already been informed, that several of the principal electric light companies commenced to promote a "Mutual Carbon Manufacturing Company," with the intention of supplying their own wants. The carbons are chiefly made from the coke of petroleum and naphtha, and it was proposed by the syndicate to take the entire petroleum-coke product of the Standard Oil Company, who are the largest producers of the coke in the States. Whether this scheme will be carried out now that the Cleveland "ring" has collapsed remains to be seen. One company, at any rate—the Thomson-Houston—

Digitized by Google

has started carbon making on its own account. Prices have again fallen to the old figures, and as it appears to be admitted that these rates cannot possibly be remunerative to the makers, it is to be regretted that the combination sacrificed their interests in a foolish attempt to obtain a purely fancy price, the result of which might have been foreseen. It seems, moreover, to have been understood that the users would not have objected to a moderate advance of $2 or $3 per thousand.

FINANCIAL CONDITION OF THE ELECTRIC LIGHTING COMPANIES.—The following paragraph has appeared in the daily press. The facts are gleaned from *Burdett's Official Intelligence*, published under the sanction of the committee of the Stock Exchange:—"Anglo-American Brush Electric Light, with a capital of £800,000 in £10 shares, in February, 1884, by the depreciation in the assets of the Company £5 per share was written off, reducing the capital to £400,000; the £5 on which £3 is paid present price £1. 10s. to £2; £5 fully-paid £3 to £4, dividend 12th February, 1886, 2 per cent., nothing since on half the original capital. Maxim-Weston Electric Company, established in 1881 as the Electric Light and Power Generator, authorised capital is now £125,000 divided into 500,000 shares of 5s. each. The nominal value of each share was reduced by resolution in May, 1884, from £1 to 10s., and again in February, 1886, from 10s. to 5s. Present price of shares 2s. 6d. to 5s., dividend paid in February, 1886, on reduced capital 7½ per cent., February, 1887, 5 per cent. Electric Sun Lamp and Power Company in liquidation; Swan United Electric Light Company; Swan and Edison. The Edison Company made over to the new Company all their asssets for £125,000. Mr. Edison is entitled to a deferred interest. The amount of interest due on these shares 30th June, 1886, was £71,887. Profit on year's working, 1885-6, £24. No dividend has yet been paid. There is a mortgage of £20,000 on Company's freehold property. Shares £3½ paid present price £1¼ to £1½."

NAVAL AND MILITARY DEFENCE.—Under the signature of "Admiral," the following letter has appeared in one of our daily contemporaries:—"In your report upon the Naval Review you declared electricity to be of greater power than armies and navies. The want of this power has been clearly proved in to-day's papers, which ask, 'Why did not the coast-guard at Dungeness telegraph to Captain Long at Deal, that the enemy's fleet was passing?' Why? Because the Admiralty has no telegraphic system. The Admiralty should be in direct telegraph communication with all coastguard stations, which in war time would act as sentinels round our extensive coast and double the protecting power of our fleets. The same may be said of the army. There is no telegraph communication to all the barracks and isolated forts throughout the kingdom. The artillery are not exercised in embarking their guns on the railway, so, if they had been wanted at Falmouth, they would probably (through loss of time) have arrived there to find the enemy well established. A few telegraph wires and the necessary knowledge for the officers and sergeants to work the telegraph machines, would render our army and navy ten times more effective. Take as an instance, Horfield Artillery Barracks, three miles from Bristol; telegraph wires pass about a dozen yards from barrack wall; nearest telegraph station about half a mile distant, closed at night. Comment is unnecessary, perhaps useless. Nothing will be done till the enemy is hammering at our doors, and then it will be too late, as Fremantle has proved that even London is not safe."

THE AMERICAN INSTITUTE ELECTRICAL EXHIBITION.—Blank application forms for space to display electrical appliances at the American Institute Electrical Exhibition, to be held in New York City, September 28th to December 3rd next, are now being sent out by the secretary, Joseph P. Wetzler. The office of the secretary is at room 175, Potter-building. The classification of the electrical exhibition shows six sections as follows:—*Section I.*—"Production of Electricity."—1. Dynamo and magneto-electric machines. 2. Primary batteries. 3. Thermo-electro apparatus. 4. Static electric apparatus.—*Section II.*—"Apparatus Requiring Powerful Currents."—1. Electric motors and transmission of power. 2. Electric railways. 3. Storage batteries. 4. Electric illumination. 5. Electro-metallurgy and electro-chemistry. 6. Miscellaneous application of powerful currents.—*Section III.*—"Apparatus Requiring Comparatively Weak Currents.—1. Fire and burglar alarms, annunciators, watchmen's time detectors, electric bells, &c. 2. Electric telegraphs, telephones, microphones, photophones and radiophones, and other apparatus for electrical communication. 3. Electric registering and signalling apparatus. 4. Application of electricity to the mechanic arts. 5. Applications of electricity to heating and ventilation. 6. Electric clocks and time telegraphs. 7. Electric medical apparatus of all descriptions. 8. Application of electricity to writing and printing. 9. Electrical toys. 10. Miscellaneous applications of small currents. *Section IV.*—"Electric Conductors."—1. Electric light and power conductors. 2. Telegraph and telephone wires and cables. 3. Insulating materials, electrical joints and connections. 4. Electric underground wire systems. *Section V.*—"Electrical Measuring Apparatus."—1. Voltmeters and ammeters. 2. Galvanometers, rheostats, &c. 3. Condensers, switches, keys, &c. *Section VI.*—1, Historical and miscellaneous exhibits. 2. Educational and bibliographical.

THE TELEPHONE IN CHINA.—The *Central News* is enabled to give an outline of the negotiations which have led up to the recently reported concessions by the Chinese Government to an American syndicate. During the past winter Mr. Wharton Barker, a Philadelphia capitalist, succeeded in interesting individual members of the Chinese Legation at Washington in the advantages to be derived from the extended use of the telephone in China. A number of exhibition tests were made between New York and Washington for the purpose of demonstrating to the Chinese the facility of long-distance communications by means of the telephone under certain conditions. The members of the Legation and other prominent Chinamen then in America conversed with ease between these two points, and were deeply impressed with the remarkable results obtained. The outcome of these tests was the formation of a syndicate for the purpose of proving in China what has already been demonstrated in America. An expedition was arranged with Count Mitkiewitz as the diplomatic head—he also representing the capital—and Mr. Barberie as chief electrician. Early in March material and telegraphic engineers were despatched in a vessel *via* the Suez Canal. Later Count Mitkiewitz and Mr. Barberie went to China *via* San Francisco. A telegraph line, having its headquarters at Pekin, was constructed, and the New York and Washington telephone experiment repeated to the satisfaction of the Chinese authorities. The Morse system of telegraphy was also successfully illustrated, and the concession to Mr. Barker and his friends followed. The railway and banking concessions have, however, not yet been made, and are merely put forward as possibilities. The American silver people may enter the telephone enterprise in the hope of ultimately getting banking concessions, and railway contractors may associate themselves with, and Barker with a similar hope. It can be stated, how with the

Digitized by Google

nothing further than telephone or telegraph concessions have been granted, and that Mr. J. Gould has no interest in the matter.

PRIMARY BATTERY SPECULATIONS.—How much longer, we wonder, is electricity to be made the happy hunting ground of needy speculators and adventurers? We do not hesitate to say that the numerous attempts which have been made within the last twelve months to float primary battery companies, not one of which is at the present time doing a legitimate trade, constitute a most discreditable chapter in the history of electrical finance. An attempt is now being made to get the public to subscribe £100,000 for the patent rights of a nitrate of soda battery. We are content to receive Prof. S. P. Thompson's bare word for the fact that the battery may be taken to be a decent specimen of its class. It is, however, necessary to observe that in the learned professor's remarks, which are made to figure so prominently in the prospectus of the company, he confined himself almost entirely to an emphatic assertion of the value of electric safety-lamps in mines—a point upon which nearly every one is agreed, but which has nothing to do with the technical or commercial merit of the battery in question; indeed, as for the technical features of the cell, no information has yet been made public. "The battery is acknowledged by the press," so the advertisements inform us, "to be the simplest and most effective electric battery that has yet been invented." The daily press is, of course, fully recognised as the supreme authority upon the point in question; as for ourselves (and we may include our technical contemporaries in the statement), it would appear that the promoters prefer not to run the risk of submitting the cell to an independent opinion. We should like to know to what extent (if any) the shares of this company have been taken up by anyone who is capable of forming an independent opinion upon the relative, not to say the absolute, value of the patents. In the present state of electro-chemical science we have no hesitation in saying that it is impossible to devise a primary cell which shall have a commercial value anywhere approaching £100,000. So long as zinc is burned as fuel with a resulting E.M.F. of a couple of volts (approximately) it is impossible to admit that any form of battery—whatever else its merits may be—can possess such an enormous superiority over everything hitherto invented as would justify an estimate of its value amounting to £100,000, or a half, or a quarter, or perhaps a tenth of that sum.

OVERHEAD LINES FOR ELECTRIC TRAMWAYS—ACCIDENT IN AMERICA.—At Montgomery, Alabama, eleven miles of street railway lines are worked by electric motors, the current being taken off from an overhead copper line. One of the disadvantages of that system—which it may be well to state has never been adopted in this country—is that the overhead wire cannot be covered with any insulating material, consequently if the wire does give way the results may possibly be serious. This possibility has just been exemplified at the expense of Governor Seay. The incident is thus reported in a local journal:—"Governor Seay was the victim of a peculiar accident this afternoon. He and his private secretary, J. K. Jackson, were driving down the main thoroughfare of the city when one of the guy wires which supported the overhead cable of the electric street railway broke and fell to the ground, striking the Governor's horse. The wire was heavily charged with electricity, and the horse, becoming entangled, was shocked and burned to death in a few minutes. A second later the wire would have struck the Governor and Mr. Jackson instead of the horse." If this unfortunate mishap had occurred been our own country, the sermons which would have been at two o'clock by the daily press can easily be imagined. In America they take these things very quietly. The *Philadelphia Press*, for instance, after making a single characteristic observation, passes on without further ado to congratulate the citizens on their rapid progress in the arts of civilisation. The following is the reflection which suggests itself to the Philadelphian mind:—"The announcement that Governor Seay, of Alabama, came near meeting his death through the fall of an overhead cable of the Electric Street Railway in Montgomery is an indication of the rapidity with which electricity is being adopted as a means for propelling cars in streets." We may as well quote the conclusion of the article, which reads the lesson that we have recently been endeavouring to enforce in this country:—"The substitution of some more efficient means for propelling street cars than the slow, costly, and cruel method now most in vogue seems certain to come soon. Humanity, if nothing else, ought to bring this about. The sufferings of street-car horses in the heat of summer and during the storms of winter ought to touch the hardest heart, but unfortunately trade does not take into account the sufferings of dumb beasts provided the balance is on the right side of the ledger. It is only by showing that there will be a larger balance on that side that a substitution of mechanical force for horse flesh will be made. Let us hope that that time is near, and that by the progress in invention the sympathies of the humane will no longer be excited by the tugging and straining under the goad of so useful and intelligent an animal as the horse."

SOPRANO *v.* BASSO FOR THE TELEPHONE SERVICE.—From the most elementary theory of the telephonic transmission of sound we learn that upon a line of given resistance, and given permittance (or capacity) and inductance, the distortion of the current waves increases with the rapidity of vibration, or the pitch of the sound; while, on the other hand, the amplitude of the current wave, on which depends the volume of sound heard in the receiver, varies inversely with the pitch. From these considerations, it might be argued that the male voice should prove decidedly better than the female for telephonic purposes. In practice, we know that this is not the case, for although certain male voices do render themselves remarkably well, yet the general average is, if anything, in favour of the female voice. Even if this latter opinion be disputed, it will, at any rate, be admitted that there is no such marked superiority on the masculine side as the theoretical considerations would lead us to expect. The explanation of this discrepancy has received considerable assistance from recent developments of acoustic theory at the hands of Herr Grassman, and by the experiments of Herr Lahr; the result is the more interesting because the explanation is arrived at, not by any impeachment of accepted electrical laws, but, as we have just indicated, by an addition to our knowledge of acoustics. It is already well known that the *timbre* ("clang-tint," as Tyndall proposed to call it), which we recognise in the same tone when sounded upon different musical instruments, or by different human voices, is due to the presence, or the greater relative prominence, of the different harmonic overtones by which the fundamental is accompanied. In the same way it has long been known that the various vowel sounds, even when pronounced by the same voice in the same tone, are each accompanied by a distinct and characteristic set of overtones. It has also more recently been shown by Lahr that the overtones for one and the same vowel are subject to variation both in pitch and in intensity, according to the inflection with which it may be uttered, and they change also with the register of the voice. So far we have perhaps learnt little which our previous knowledge might not have enabled

Digitized by Google

us to deduce as a corollary. Now, however, Grassman steps in and asserts from theory, while Lahr demonstrates by experiment, that the characteristic overtones of the bass voice are relatively higher in pitch, and therefore subject to more rapid "distortion" in a telephone circuit than those of the female; in other words, a soprano or contralto voice renders all its vibrations, fundamental tones and harmonics, or overtones as well, within a very much narrower range upon the scale, and thus the various tones suffer pretty much to the same extent, so that the characteristics of the voice are recognisable over a correspondingly greater telephonic range. The male voice, on the other hand, requires for perfect transmission the preservation of multitudinous tones extending over well nigh the whole length of the audible scale, and this we know is only possible telephonically on condition that the resistance, the permittance, and the inductance of the circuit are all either negligibly small, or else that they should bear certain complex relationships to one another which it is not within the scope of this note to set forth. They may, however, be discovered in the papers of Mr. Oliver Heaviside by those who care to seek.

PHOTOMETRY.—MR. DIBDIN ON THE PENTANE STANDARD.—The report on Photometry, presented by Mr. W. J. Dibdin to the Metropolitan Board of Works, constitutes one of the most important papers on the subject which has hitherto appeared; it comprises an elaborate series of tables containing the results of over 20,000 recorded observations. The whole of the report is of interest, but we are unable to do more than reproduce the most important portion, which is as follows:—"In selecting a substitute for the present legal candle, care should be exercised to ensure that it complies with the three main conditions which apply to the present standard, viz.: 1. That it should have a definite combustible material; 2. That the condition in which that combustible material exists at the time of use should be under control and capable of inspection for verification. 3. That the rate of combustion, and the manner in which it is effected, should be readily and accurately observed. By applying these considerations to each of the proposed standards, a guide is at once obtained for the selection of the most suitable. The pentane air gas, as devised by Mr. A. Vernon Harcourt, the Keates lamp, and the amyl-acetate flame of Herr von Hefner-Alteneck, all answer to the requirements of these conditions; while the Methven screen, the pentane lamp, the ten candle test, and its improved form, which I have called the 'Pentane Argand,' although each giving most excellent results in practice, fail to comply with these requirements, as they each depend upon a purely arbitrary rate of consumption of combustible material, coupled with a definite height of flame, but no check is afforded by means of which an involuntary error in the setting of the flame by the observer can be afterwards detected. Of those proposals answering to the above conditions, the Keates sperm oil lamp has one serious defect—in that the wick, when once used, cannot be re-ignited without fresh adjustment or renewing, and thus a discrepancy is apt to occur. Furthermore, the practical difficulty found by various operators in obtaining a flame of uniform character seems to have been more serious than I had hitherto been led to suspect; and to such an extent has this been experienced that I am compelled to put it on one side in face of the more easily managed pentane air gas and other proposed substitutes for candles. The amyl-acetate lamp has many points which entitle it to very careful consideration, not the least among these being its extreme simplicity and portability. It is, in fact, only a carefully constructed spirit-lamp; and in actual work has given most admirable results. Unfortunately, however, the colour of the flame is its one weak point; and for this reason I am of opinion that it is not the most suitable for adoption as the standard. On the other hand, I have found the pentane air gas to comply with every demand made upon it, and to answer to the full all the claims made for it by the inventor. The facts brought out by this inquiry have shown that the method of preparing the air gas is at once easy and safe; that the measurement of the volume of gas used is simple and reliable; that the adjustment of the height of the flame is a matter of certainty; its steadiness all that can be desired, when due care is taken and proper apparatus employed; and that the colour of the light afforded is precisely the same as that of the standard comparison gas-flame. With reference to the steadiness of the flame, I can fully bear out all I formerly said of it. During the exhaustive trials to which it has been subjected, not a single test has been lost or doubted from this cause. The only necessary precaution was to avoid irregular air currents; the photometer chamber in which it was burning being so arranged as to provide a large volume of air moving at a low speed. This was done by closing the top of the chamber—which was 2ft. 8in. high, by 18in. by 21in.—by means of a board perforated with a circular aperture 4 inches in diameter. The bottom of the chamber was left open at the back and front about 6 inches from the table on which it stood. It was found that such an arrangement was also advantageous in the case of the pentane and amyl-acetate lamps. Should it be desired to use the flame in an unsuitable position as regards draught, the use of the chimney (as arranged by the inventor) entirely obviates all difficulty from unsteadiness, and renders the flame absolutely steady and free from the slightest sign of vibration or swaying. This observation also applies to the pentane lamp, which affords a flame of precisely similar character to that of the pentane air-gas. The improved pattern of this lamp, which is in no way altered as regards the principle of its operation, but is improved merely in matters of detail and adjustment, has afforded remarkably good results, and when it is properly working gives results identical with the air-gas flame. Table showing the total number of tests made, and the total and percentage numbers within 1 per cent. of the mean (excluding those given in the first report):—

Standard.	Total No. of Tests.	No. within 1 per cent. of the Mean.	Percentage No. within 1 per Cent. of the Mean.
Candles	454	154	34
Keates's lamp	244	98	39
Pentane	468	373	80
Methven	283	211	74
Ten-candle test	49	43	88
Pentane Argand	243	212	87
Amyl-acetate	225	206	90
Pentane lamp	154	150	97
Total	2,120		

In view of the unmistakable results of the exhaustive series of tests conducted during this inquiry, I recommend that the committee do advise the Board to forthwith take such action as may be necessary to secure the adoption, with as little delay as possible, of the pentane air gas standard as devised by Mr. A. G. Vernon Harcourt, F.R.S., &c., as the legal standard of light in this country. As, however, many practical photometrists are of opinion that a standard of light of more than one candle is desirable for many purposes, I further recommend that when the legal substitution of the pentane unit for the present candle be made, the Board of Trade should be empowered to sanction and authorise the use of such other standards and substitutes as that Board may deem fit and proper to be used in place of and after comparison with the pentane air gas flame."

us to deduce as a corollary. Now, however, Grassman steps in and asserts from theory, while Lahr demonstrates by experiment, that the characteristic overtones of the bass voice are relatively higher in pitch, and therefore subject to more rapid "distortion" in a telephone circuit than those of the female; in other words, a soprano or contralto voice renders all its vibrations, fundamental tones and harmonics, or overtones as well, within a very much narrower range upon the scale, and thus the various tones suffer pretty much to the same extent, so that the characteristics of the voice are recognisable over a correspondingly greater telephonic range. The male voice, on the other hand, requires for perfect transmission the preservation of multitudinous tones extending over well nigh the whole length of the audible scale, and this we know is only possible telephonically on condition that the resistance, the permittance, and the inductance of the circuit are all either negligibly small, or else that they should bear certain complex relationships to one another which it is not within the scope of this note to set forth. They may, however, be discovered in the papers of Mr. Oliver Heaviside by those who care to seek.

PHOTOMETRY.—MR. DIBDIN ON THE PENTANE STANDARD.—The report on Photometry, presented by Mr. W. J. Dibdin to the Metropolitan Board of Works, constitutes one of the most important papers on the subject which has hitherto appeared; it comprises an elaborate series of tables containing the results of over 20,000 recorded observations. The whole of the report is of interest, but we are unable to do more than reproduce the most important portion, which is as follows:—"In selecting a substitute for the present legal candle, care should be exercised to ensure that it complies with the three main conditions which apply to the present standard, viz.: 1. That it should have a definite combustible material; 2. That the condition in which that combustible material exists at the time of use should be under control and capable of inspection for verification. 3. That the rate of combustion, and the manner in which it is effected, should be readily and accurately observed. By applying these considerations to each of the proposed standards, a guide is at once obtained for the selection of the most suitable. The pentane air gas, as devised by Mr. A. Vernon Harcourt, the Keates lamp, and the amyl-acetate flame of Herr von Hefner-Alteneck, all answer to the requirements of these conditions; while the Methven screen, the pentane lamp, the ten candle test, and its improved form, which I have called the 'Pentane Argand,' although each giving most excellent results in practice, fail to comply with these requirements, as they each depend upon a purely arbitrary rate of consumption of combustible material, coupled with a definite height of flame, but no check is afforded by means of which an involuntary error in the setting of the flame by the observer can be afterwards detected. Of those proposals answering to the above conditions, the Keates sperm oil lamp has one serious defect—in that the wick, when once used, cannot be re-ignited without fresh adjustment or renewing, and thus a discrepancy is apt to occur. Furthermore, the practical difficulty found by various operators in obtaining a flame of uniform character seems to have been more serious than I had hitherto been led to suspect; and to such an extent has this been experienced that I am compelled to put it on one side in face of the more easily managed pentane air gas and other proposed substitutes for candles. The amyl-acetate lamp has many points which entitle it to very careful consideration, not the least among these being its extreme simplicity and portability. It is, in fact, only a carefully constructed spirit-lamp; and in actual work has given most admirable results. Unfortunately, however, the colour of the flame is its one weak point; and for this reason I am of opinion that it is not the most suitable for adoption as the standard. On the other hand, I have found the pentane air gas to comply with every demand made upon it, and to answer to the full all the claims made for it by the inventor. The facts brought out by this inquiry have shown that the method of preparing the air gas is at once easy and safe; that the measurement of the volume of gas used is simple and reliable; that the adjustment of the height of the flame is a matter of certainty; its steadiness all that can be desired, when due care is taken and proper apparatus employed; and that the colour of the light afforded is precisely the same as that of the standard comparison gas-flame. With reference to the steadiness of the flame, I can fully bear out all I formerly said of it. During the exhaustive trials to which it has been subjected, not a single test has been lost or doubted from this cause. The only necessary precaution was to avoid irregular air currents; the photometer chamber in which it was burning being so arranged as to provide a large volume of air moving at a low speed. This was done by closing the top of the chamber—which was 2ft. 8in. high, by 18in. by 21in.—by means of a board perforated with a circular aperture 4 inches in diameter. The bottom of the chamber was left open at the back and front about 6 inches from the table on which it stood. It was found that such an arrangement was also advantageous in the case of the pentane and amyl-acetate lamps. Should it be desired to use the flame in an unsuitable position as regards draught, the use of the chimney (as arranged by the inventor) entirely obviates all difficulty from unsteadiness, and renders the flame absolutely steady and free from the slightest sign of vibration or swaying. This observation also applies to the pentane lamp, which affords a flame of precisely similar character to that of the pentane air-gas. The improved pattern of this lamp, which is in no way altered as regards the principle of its operation, but is improved merely in matters of detail and adjustment, has afforded remarkably good results, and when it is properly working gives results identical with the air-gas flame. Table showing the total number of tests made, and the total and percentage numbers within 1 per cent. of the mean (excluding those given in the first report):—

Standard.	Total No. of Tests.	No. within 1 per cent. of the Mean.	Percentage No. within 1 per Cent. of the Mean.

Pentane lamp	154	150	97
Total	2,120		

In view of the unmistakable results of the exhaustive series of tests conducted during this inquiry, I recommend that the committee do advise the Board to forthwith take such action as may be necessary to secure the adoption, with as little delay as possible, of the pentane air gas standard as devised by Mr. A. G. Vernon Harcourt, F.R.S., &c., as the legal standard of light in this country. As, however, many practical photometrists are of opinion that a standard of light of more than one candle is desirable for many purposes, I further recommend that when the legal substitution of the pentane unit for the present candle be made, the Board of Trade should be empowered to sanction and authorise the use of such other standards and substitutes as that Board may deem fit and proper to be used in place of and after comparison with the pentane air gas flame."

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

At a time when the electrical world has lately been engaged in the celebration of the Jubilee of the Electric Telegraph it will not be inopportune to take a survey of the rise and progress in our own country of one of its latest developments, namely, Telephony. It is not our intention to enter upon the interminable controversy as to who should or should not be regarded as the first, true and original inventor of the telephone, it will be sufficient for our purpose to state that as a commercial idea Telephony has now almost completed the first decade of its existence, and is therefore rather more than forty years younger than the telegraph. The English patent in which the invention of Prof. Graham Bell is set forth bears date the 9th December, 1876; the specification of Edison's carbon transmitter is dated the 30th of the following July, and the first public exhibition in this country of a working telephone was made by Mr. Preece at the Plymouth meeting of the British Association in the year 1877. At the meeting of the British Association held the previous year in Glasgow, Sir William Thomson had given an account of the researches in which Prof. Graham Bell was at that time engaged, and had excited great curiosity by the exhibition of an instrument (since known to fame as the Glasgow receiver), in which a diaphragm was attached at one side to the end of a cylindrical magnet. This receiver was exhibited in public prior to the issue of the patents, and hence is not covered by the specification; it was, however, of little or no practical value, and even Sir W. Thomson did not succeed in getting it to talk intelligibly. The exhibition by Mr. Preece twelve months later was, therefore, the first occasion on which the telephone spoke in public in this country.

Whoever may have been the first inventor of the telephone it is at least certain that the art of telephony is of American birth, and though its genealogy is to some extent to be traced in the annals of British science, yet we cannot claim as large a share in its origin as is justly awarded us in the earlier art of telegraphy. It is, however, well known that Prof. Graham Bell, although long resident in the United States, is by birth of British nationality, and when, in addition to this, we consider the indisputable fact of the priority of Prof. Hughes's discovery of the microphone, we have abundant reason for self-congratulation upon the part which our countrymen have borne in the origination of one of the most mysterious and beautiful applications of modern science, and one which from its flexibility and universality of adaptation gives promise of a future of as yet unknown importance.

At Plymouth, in the instruments exhibited by Mr. Preece, the Bell receiver was used also as a transmitter, the advantages of the carbon transmitter not having as yet been made known. The results obtained were thus comparatively feeble in character, and led for the time to the conclusion that the instrument could only be regarded as a scientific toy. It was this misconception which in all probability led to the rejection of the patent rights when offered to the British Post Office. The subsequent action brought by the department against the telephone companies (to which we shall refer later) is sufficient proof that a decided, though certainly an excusable, mistake was made in this refusal. What the present state of telephony would have been had the patents passed into the possession of the Government is scarcely a profitable subject for speculation; nor would it be altogether safe to assume that the Post Office would repeat in London the success which it has of late years undoubtedly achieved in Newcastle-on-Tyne

Be this as it may, however, about the end of 1877 Mr. James Brand proved himself more far-sighted or more enterprising than the Government, and succeeded in forming the Bell Telephone Company, which was registered in the following year, and of which Mr. Brand was the first chairman. The Bell Company was still without an efficient transmitter, the exchange system had scarcely been thought of, and it was by no means [illegible] everyone that the invention was capable of bearing a commercial value. However, the instruments were easily and cheaply made, and as the retail price was fixed at starting at £70 per pair, it did not need a very large volume of business in order to make a profitable return upon the investment. The first instruments made in this country, while the company was still in process of formation, were turned out by the Silvertown India Rubber and Gutta Percha Company, and before the close of 1877 a set of these was erected at Osborne by command of Her Majesty the Queen.

In the course of the following year—that is, not long after the formation of the company—it became evident that the sale of telephones for private use could not at any price be made the basis of so large a business as had been hoped for, and concurrently with the introduction of the "exchange" system (an American development) a resolution was arrived at which proved to be of the utmost importance to the future of the company, and, indeed, to the whole future of telephony in this country so long as the patents remain in force. The company determined to cease entirely from the sale of their instruments, and from that day to this no Bell telephones have legitimately changed hands save a certain number which had already been sold outright.

This action of the Bell Company has naturally given rise to unlimited grumbling, and is often harshly criticised; but while there can be no question as to the commercial shrewdness by which the policy was dictated, it should also be remembered for one thing that their instruments are of a description which it is excessively easy to pirate, and if indiscriminate sales were allowed it would be a matter of the greatest difficulty to ensure the payment of the royalties which the owners of the patent are entitled to charge. Our readers do not need to be assured that we are by no means in all respects apologists of the conduct of the telephone companies, but in this matter we are inclined to think that they pursued a sound policy, to which no valid objection can be made.

In the meantime it had become evident that while the Bell telephone employed as a receiver posseses a delicacy and a flexibility which remains to this day nothing short of a marvel, yet it is quite incapable of generating an E.M.F. of suitable strength to be an efficient transmitter for exchange work. Edison had early perceived this weakness, and had set himself to devise a type of transmitter which would permit the employment of a battery current of any required strength. Not content with this, he determined also to produce some form of receiver in which the necessary vibration of the diaphragm should be actually enforced by mechanical means, and the function of the current should be reduced to the regulation or adjustment of these mechanical vibrations. The latter part at least of the problem so set was sufficiently remote from the available resources of electrical science to merit any amount of scepticism as to the possibility of its accomplishment. But the indomitable perseverance and the fertility of resource of the American inventor triumphed over every difficulty, and before the close of the year 1878 the carbon transmitter had been re-invented, and the remarkable chalk-cylinder loud-speaking receiver had been brought into existence. That an electrical apparatus should be founded upon a property of chalk is certainly surprising. Edison was, however, aware that under certain conditions the friction between a moistened chalk cylinder and a tongue of platinum was lessened when a current passed through the point of contact in proportion to the strength of the current. This was sufficient foundation for his inventive capacity to build upon, and not only the loud-speaking telephone, but the equally remarkable phonograph was the almost immediate result. Without wishing in any way to detract from the credit due to Edison, it is, however, only fair to recollect that a telegraph based upon the variation of a frictional resistance traversed by the current was many years ago proposed by Bain, the inventor of the chemical telegraph, and to him the honour of the discovery of *one* of the principles employed by Edison in his receiver is certainly due.

[illegible] company was formed in this country to work these in[illegible] to compete with the Bell Company in the formation [illegible]xchanges. For a while the two companies proceeded

Digitized by Google

on parallel lines, it being perfectly clear that their respective patents in no way interfered. But the Bell Company, realising the necessity of improving their transmitter, now adopted the so-called "Blake" instrument, in which a battery was employed in conjunction with a platinum-carbon contact. This was promulgated as a modification of Prof. Hughes's microphone, a discovery which, although of immense importance, he had magnanimously refused to patent. The Edison Company, however, asserted that Blake had infringed their rights in carbon transmitters, and legal proceedings were commenced. Before matters had reached any advanced stage the experience of the Edison Company had led them to perceive that, notwithstanding its louder tones, the complication of clockwork in their receiver, the necessity for keeping the cylinder moist, and the difficulty of maintaining a proper adjustment, placed them at a distinct disadvantage, which would perhaps more than counterbalance the superiority of their transmitter, even if they obtained the exclusive right to the use of carbon. In fact, notwithstanding the beauty and ingenuity of the Edison receiver, it never was a good commercial appliance, and has now, so far as we are aware, entirely disappeared from the scene.

These considerations on either side led to a withdrawal from legal proceedings and the foundation on May 1st, 1880, of a new company which bought up both the Edison and the Bell patents, and became known under the title of the UNITED TELEPHONE COMPANY. The two original companies went into voluntary liquidation, and the board of the United Telephone Company was in part made up of directors from both the former, Mr. Brand retaining his position as chairman. The Bell Company received £200,000 as the entire purchase money, and the Edison received £115,000. At the time of the amalgamation the annual rate of subscription to the Bell Telephone Exchange had been fixed at £20, and about 400 subscribers were in connection. The Edison Exchange had about 200 subscribers, and were charging £12 per annum. It should also be mentioned that the officers of the two companies were retained to form the working staff of the new company, and Mr. Thomas Fletcher, the electrician to the Bell Company from the commencement of its operations, was appointed chief engineer to the United. The Edison instruments were replaced by the Bell receiver and the Blake transmitter, and the subscription was fixed at £20 per annum.

Shortly after the formation of the United Telephone Company Major Joseph Bond Morgan, who had been chiefly instrumental in making the telephone a practical and commercial success at Liverpool, where an exchange was already at work, became managing director of the company, a position which he still continues to hold. The Liverpool exchange, it may be mentioned, was at that time, and has continued to be ever since, the largest in this country—that is to say, it possesses the largest number of subscribers connected with a single centre.

(To be continued.)

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 201.)

The weights of the various parts of the foregoing machine will be as follows:—

Armature core	105 lbs.
Field-magnets	500 ,,
Armature winding	22 ,,
Field-magnet winding	78 ,,

Thus, the total weight of materials required in the electrical construction of the machine is—

Iron	605 lbs.
Copper	100 ,,

The electrical resistance of the armature will be ·0448 ohm, in which, with a total current of, say, 105 amperes, the loss would be 497 watts per second. Checking this figure by the surface presented by the armature core, and allowing 1 watt per second per square inch, we get 503 watts per second total loss.* From the current density and weight of copper in the field winding we find the loss there to be 266 watts per second. The total rate of work is thus, say, $10,000 + 770 = 10,770$ watts per second, and the electrical efficiency is $\frac{10000}{10770} = 93$ per cent.

With regard to the electrical efficiency of dynamos, we have seen that the work done in the armature winding in a given time can be expressed by the product $a R^2$, where a is constant for all machines of one type. Similarly, the work done in the field winding must be in proportion to the cooling surface. It has been shown that the length of the magnet cores varies as $R^{\frac{2}{3}}$, where μ is supposed to have an average value, or, more strictly, where μ is constant. Where μ varies, the length of cores will vary as $\frac{R^{\frac{2}{3}}}{\mu^2}$, the depth of winding being independent of variations in μ. The sectional area of the cores varies as R^2; thus the surface varies as $\frac{R^{\frac{5}{3}}}{\mu^2}$, and the work done in a given time is $b\frac{R^{\frac{5}{3}}}{\mu^2}$ where b is constant. Finally, the total work in the circuit has been shown to vary as $\mu R^{\frac{5}{2}}$ with constant peripheral velocity, and can be written $c\mu R^{\frac{5}{2}}$.

The electrical efficiency is thus:—

$$\text{Efficiency} = \frac{c\mu R^{\frac{5}{2}} - a R^2 - \frac{b R^{\frac{5}{3}}}{\mu_1^2}}{c\mu R^{\frac{5}{2}}}$$

where μ and μ_1 refer to the armature and field winding respectively.

The above expression can be of no practical use unless μ and μ_1 are written as functions of R, and under certain conditions this can can be done. We will deal with the two cases which occur most frequently in practice, viz., those of constant E.M.F. and of constant current. The latter conditions will not need any further calculation because μ will be constant, whilst the constants a, b, and c can be found when once a machine is designed.

The condition of constant E.M.F., however, introduces important modifications.

We have from equation (7) the section of wire

$$A \propto \frac{\mu^2 R^2}{N},$$

and from (6)

$$N \propto \frac{1}{n R^2},$$

but with constant peripheral velocity

$$n \propto \frac{1}{R};$$

$$\therefore N \propto \frac{1}{R} \text{ and } A \propto \mu^2 R^3$$

we will write $A = d\mu^2 R^3$ . . . . . (1*b*)

where d is a constant.

With regard to the form of the section A, it is clear that the greatest advantage will be secured when it is square; in any case, μ could be written as a function of $\sqrt{A}$, and since practical facilities do not forbid the use of square wire, we shall put

$$\mu = \frac{\sqrt{A}}{\sqrt{A} + \cdot 05}.$$

$$\therefore \mu^2 = \frac{A}{A + \cdot 1\sqrt{A} + \cdot 0025},$$

substituting in (1*b*)

$$\mu^2 = \frac{d\mu^3 R^3}{d\mu^2 R^3 + \cdot 1\sqrt{d}\,\mu R^{\frac{3}{2}} + \cdot 0025};$$

* Or allowing ·9 watt per sq. in. only, the total current must be restricted to 100 amperes.

Digitized by Google

thus $$d\,R^3\mu^2 + \cdot1\sqrt{d}\,R^{\frac{3}{2}}\mu + \cdot0025 - d\,R^3 = 0.$$

Whence $$\mu = \frac{-\cdot1\sqrt{d}\,R^{\frac{3}{2}} \pm 2\,d\,R^3}{2\,d\,R^3};$$

and since the + sign only need be considered

$$\mu = 1 - \cdot05\,d^{-\frac{1}{2}}\,R^{-\frac{3}{2}} \quad . \quad . \quad . \quad . \quad . \quad (2b)$$

In a similar manner it can be shown that

$$A = d\,R^3 - \cdot1\sqrt{d}\,R^{\frac{3}{2}} + \cdot0025. \quad . \quad . \quad . \quad (3b)$$

The total work done in the circuit per second will now be written $$W = c\,(R^{\frac{5}{2}} - \cdot05\,d^{-\frac{1}{2}}R) \quad . \quad . \quad . \quad . \quad (4b)$$

The section of wire in the field-magnets will be $A = e\,\mu_1^2\,R^3$ e being a constant; and since the section is to be taken as circular

$$* \quad \mu_1^2 = \frac{\pi}{4} \cdot \frac{A}{A + \cdot04\sqrt{A} + \cdot0004}$$

whence by making the proper substitutions and solving the quadratic as before

$$\mu_1 = \frac{-\cdot04\sqrt{e}\,R^{\frac{3}{2}} \pm \sqrt{\pi e^2 R^3}}{2\,e\,R^3}$$

$$= \frac{\sqrt{\pi}}{2} - \cdot02\,e^{-\frac{1}{2}}\,R^{-3} \quad . \quad . \quad . \quad . \quad . \quad (5b)$$

and $$\mu_1^2 = \frac{\pi}{4} - \cdot02\sqrt{\pi}\,e^{-\frac{1}{2}}\,R^{-\frac{3}{2}} + \cdot0004\,e^{-1}\,R^{-3}$$

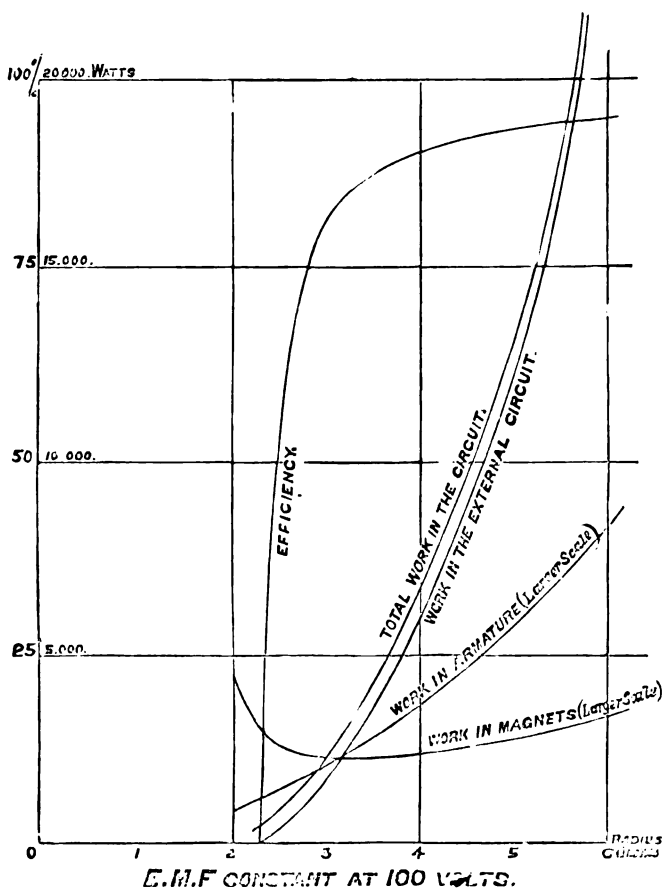

FIG. 14.

The electrical efficiency can now be expressed as a function of R only, and it is

$$\text{Eff.} = \frac{c(R^{\frac{5}{2}} - \cdot05\,d^{-\frac{1}{2}}R) - a\,R^2 - b\left(\frac{R^{\frac{5}{2}}}{\frac{\pi}{4} - \cdot02\sqrt{\pi}\,e^{-\frac{1}{2}}\,R^{-\frac{3}{2}} + \cdot0004\,e^{-1}\,R^3}\right)}{c(R^{\frac{5}{2}} - \cdot05\,d^{-\frac{1}{2}}R)}$$

Taking the E.M.F. at 100 volts, the constants a, b, c, d, and e may be deduced from the machine already designed, and are as follows:—

$$a = \frac{500}{R^2} = 23\cdot3$$

$$e = \frac{A_1}{\mu_1^2\,R^3} = \frac{\cdot00521}{\cdot504 \times 99} = \cdot000104$$

$$d = \frac{A}{\mu^2\,R^3} = \frac{\cdot0149}{\cdot533 \times 99} = \cdot000281$$

$$c = \frac{10770}{32\cdot16} = 334$$

$$b = \frac{270 \times \cdot4772}{12\cdot8} = 10\cdot1$$

In Fig. 14 a set of curves are plotted from the above figures; it will be seen from them that dynamos of this type to give 100 volts cannot be economically constructed with smaller radius than 3in., and that at a radius of 2·15in. the machine would refuse to do any work in the external circuit.

From equation (4b) we should find the output to be zero when

$$R^{\frac{5}{2}} = \cdot05\,d^{-\frac{1}{2}}R;$$

that is when $$R^{\frac{5}{2}} = 3\,R$$

or $$R = 3^{\frac{2}{3}} = 2\cdot08\text{in.}$$

The meaning of this is that at those dimensions the cross section of copper in the winding becomes zero, and μ vanishes.

As a matter of fact it would be possible to make somewhat smaller generators than here indicated, but it would be done only by using thinly insulated wire, and by increasing the speed or heating co-efficient. Smaller machines of lower E.M.F. could, of course, be made.

For the sake of convenience in reading, the curves showing the rate of work in armature and field-magnet winding are drawn to ordinates ten times higher than those to which the curves of total work are drawn; it is interesting to note that there is a point of inflexion in the field-magnet curve.

(To be continued.)

LIGHTING ENGINE FIRES BY ELECTRICITY.—At a recent meeting of the Chicago Association of Master Mechanics a communication was read from Mr. J. Leonard on the subject of "Locomotive Preparation," in which a question was raised as to the practicability of employing electricity in "firing up" locomotives with a view to economy of time and fuel. Assuming that the locomotive shed already possesses an electric lighting plant Mr. Leonard was of opinion that such an arrangement is "entirely feasible." After referring to the Cowles electric furnace, he expressed a preference for a low tension method as being safer and probably more economical; but considering that there are comparatively few railroad shops in America provided with incandescent machines, while arc circuits are plentiful, he thought it would be interesting to consider under what condition the arc lamp current could be used. The paper concludes as follows:—"1. The apparatus should be rendered perfectly safe by being heavily insulated to prevent short circuiting through the person handling it. 2. It should be fitted with flexible wires, so as to reach any part of the roundhouse; and 3. It should be small enough to readily pass in and out of the furnace door. These it seems to me are the most essential qualities that such an apparatus should possess, and I believe can be readily combined by the use of a V-shaped frame with three pairs of carbons connected in series and switch placed high enough on the two conductors to cut off the current from that part of the apparatus likely to be handled. Of course it would be necessary to properly insulate the carbons, the first charge of coal, and the apparatus itself from the end of the boiler in order to prevent the loss of current to and through the ground. This could be done by using a plate of, say, slate or asbestos for the base of apparatus, long enough to hold the coal to be ignited."

* ·02 only is allowed for covering in magnet winding.

THE OERLIKON ELECTRO-PLATING DYNAMO.

The dynamos designed by Mr. C. L. Brown, and built at the Oerlikon Engineering Works near Zurich, seem to have come into a good deal of favour upon the Continent, some seventy or eighty machines of various types having been installed within the last year or two. In general design these dynamos conform very closely to the Manchester type, the chief departure being in a direction which in our opinion scarcely commends itself as an improvement. This is in the winding of the armature, which is virtually a Pacinotti ring, but the wire, instead of lying in slots around the edge of the iron discs, is threaded through holes drilled close to the margin of the iron. The object of this arrangement is apparently to increase the mass of the armature iron in closest proximity to the field core. But although the magnetic resistance is somewhat reduced, it is apparent that the benefit thus obtained will be more or less counteracted by the fact that a certain number of lines can traverse the periphery of the armature without passing through the windings, and thus tend merely to increase the magnetic resistance of the whole of the field iron. It is clear, however, that the Oerlikon dynamos are well built and efficient machines; and we may remind our readers that they are now being shown at the Manchester Exhibition by Mr. Thwaite, of Liverpool, who has been appointed agent for this country.

The two adjoining figures illustrate the construction of an electro-plating machine of this type designed for an output of 50 horse-power at 350 revolutions, and to be capable of running day and night for considerable periods without intermission. The terminal E.M.F. amounts to 115 volts, and with a current of 440 amperes the rise of temperature in the armature after a run of 14 hours has been found to amount to about 60°C., and in the field to about 35°C. The machine is very substantially built, and weighs 6·5 tons. The field is shunt-wound, and is excited with 35,000 ampere turns, a figure which seems to be pretty high considering that there is only one layer of wire on the outside of the armature. The magnetic circuit is, however, rather long, and there would appear to be some opportunity for leakage between the horns of the pole-pieces, which extend, perhaps, a little too far. The electrical efficiency is given as 95 per cent. Fig. 1 is a central longitudinal section of the machine, and Fig. 2 is a vertical section in two planes.

THE NAVAL MANŒUVRES AND THE TELEGRAPH.

Probably the best lesson we can derive from the mimic warfare which raged on our southern and western coasts last week is that these naval manœuvres ought to become an established institution, like the Autumn and Easter manœuvres on land. Our knowledge of what took place is limited by the fact that newspaper correspondents did not accompany either the attacking or defending squadrons; but sufficient information has reached us through trustworthy channels to prove that a good deal of useful work was done on both sides; and, what is of greater importance, that some of the weak links in our system of defence were made conspicuous. Perhaps on account of the circumstance just mentioned the experiment has not been very kindly handled by the press, which is always disposed to ridicule what it has no hand in describing. According to some of these organs the naval manœuvres were not only a sham, which undeniably they were, but a farce, which they certainly were not. This matter is set at rest by a perusal of the interesting and instructive account of a naval correspondent with Sir W. HEWETT'S Division published in last Monday's *Times*. If only we had a similarly complete report from Admiral FREMANTLE'S Division some of the points in which our readers are most interested would be made clearer. But even as it is we have sufficient evidence to show that in the matter of coast defence the Electric Telegraph plays but a very insignificant part. Visual signalling from shore to ship seems to have been as perfect as between ship and ship; but between the various land points separated beyond the reach of visual signals, where, if anywhere, we should expect electric signalling to be available, either it has no existence or it was very little used.

It is asserted by a correspondent of the *Globe* that even at the important position of Dungeness, which commands the southern entrance to the Straits, there is no electric telegraph. The statement seems incredible, but receives some confirmation in the fact that FREMANTLE'S attacking squadron, after dodging and leaving the defending fleet behind off Portland, actually was sighted at Dungeness steaming on to the Nore, while a flotilla of torpedo and gunboats off Deal remained in ignorance of the fact, and was passed with impunity. This would seem to imply that Dungeness possesses no means of signalling to Deal or to Dover, close by, neither of which is distant more than fifty miles! If this is the case, then we can only suppose that the wily FREMANTLE knew it, and hope that if ever his tactics are imitated by a hostile fleet its commander will *not* know it; or, better still, that before that day arrives we shall have frightened the British Government into spending the few pounds necessary to connect Dungeness with the inland system of telegraphs.

The *Globe's* correspondent's statement is borne out in general terms by the diary of *The Times'* naval correspondent. Making all due allowance for his evident desire to explain away the dense fog, despite of fine weather, in which the movements of Admiral FREMANTLE had left the defenders, we cannot but admit the justice of his comments on the defective signalling arrangements on land. "The immense importance," he says, "for the defence of our coast of joining all our principal coast guard stations, lighthouses, &c., telegraphically is being made evident at every move we make." Incidentally he mentions that it takes a full hour to get a message through from Plymouth to Portland. Had the defence been a real one, we may reasonably conjecture that not a tenth of an hour would be lost on such a service; but the existing route is certainly circuitous, and might easily be shortened. Of course an invading fleet would steer clear of the coast stations until it made up its mind for the point of attack. But the defenders would, as they actually did in this case, send out their fast cruisers as scouts; and the vital thing would be that the scout could make direct for any coast signalling station; and that this station should in turn be able to dispatch her visual signals instantly by electric telegraph to the port in communication with the defending squadron. We say this ought to be possible, but apparently at present it is not; for the accessible points are too far apart, and they are not all provided with the electric telegraph.

It has been urged that the defenders were not adequately supported by the land forces. But this is a misapprehension. The plan was not for a landing, but for a destructive raid upon either a fortified town or shipping port, ten hours' unmolested possession to constitute a successful bombardment. In the case of Falmouth—to say nothing of what was done on the western coast—this feat was accomplished; and by availing himself of the tide when the defenders—who arrived too late, owing to defects of coast signalling—could not follow him, Admiral FREMANTLE actually sailed up the Thames and got possession of Sheerness and the Medway. Whether he could have ever got out again is another matter. Now, for such a plan of operations the land forces were not necessary, because they would have been useless. All that was necessary was to add to the strength of the signalling stations; and this we learn was actually arranged, special signalmen having been placed along the coast between the Lizard and South Foreland. We may take it, therefore, that everything was done that in the event of a sudden descent upon the South coast could possibly be done. The result, though flattering in some respects, is not

Digitized by Google

reassuring; and for one thing it is clear that our telegraphic arrangements as an instrument of national defence are far from satisfactory.

The chief service rendered to Sir W. HEWETT'S squadron was by "that very smart man," Lloyd's superintendent at the Lizard. He seems to fully answer the description given of him by his grateful admirer. Every vessel in the navy would appear to be known to him, and he penetrated their cunning disguises in a way that may naturally astonish us landsmen, seeing that they deceived all the sailors afloat in Admiral HEWETT'S squadron. But such preternaturally "smart men" are not plentiful; and, indeed, one of the enemy's ships, disguised as an ordinary paddle boat, sailed inshore between the defenders and the coast signalmen without being detected, and actually flashed a false telegram, which they innocently sent forward as genuine. At first sight this incident seems to tell against telegraphy, which lends itself to a daring ruse of that description; but in reality, if the less smart men at Tor Cross, Salcombe, could have seen with the eyes of the smarter man at the Lizard, who had spotted the pretended paddler some hours previously—in other words, if they had been in telegraphic communication with him—the impostor would have been captured instead of getting clean away, as she easily did. We have said that these manœuvres should be repeated periodically; but we hope that when next they take place such an exploit as this will be rendered impossible.

CORRESPONDENCE.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

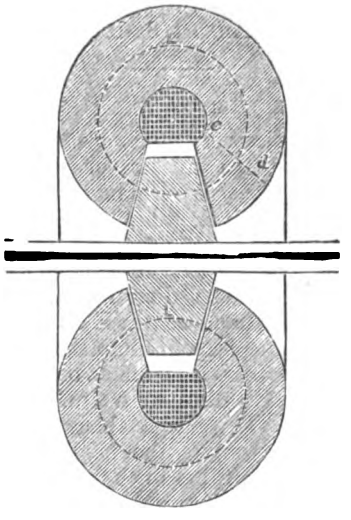
SIR: In the first paragraph of his last letter Mr. Scattergood points out that I have credited him with a meaning which he did not intend. Doubtless, he is the best judge of his own meanings, but my mistake was, I should say, a very natural one, for his first letter contained the statement that "the rotation of a cylindrical bar magnet about its axis does not induce a current in a fixed circuit situate in its field, *because the number of lines which pass through the circuit are unaltered by the magnet's rotation*, the field being symmetrical about the axis." Now, since he distinctly states his reason for the non-production of a current, the observation must be held to apply equally well to any circuit, whether fixed or not, so long as the number of lines passing through it does not change. *Ergo*, "a cylindrical magnet" (Forbes's field-magnet will do for this, and as there is no restriction with regard to contacts, we may suppose the machine to revolve around its armature) "rotated on its axis does not excite a current in a stationary conductor" (the Forbes armature) "situate in its field, while the conductor" (the armature) "itself, if rotated in the same way relatively to the magnet, does give a current." (I added the latter statement because it is well known that the Forbes machine gives a current.) Now, in neither case is there any "change in the number of lines of force embraced by the circuit." Mr. Scattergood will very likely take exception to this statement, for this is what he "emphatically" asserts is necessary in order to have any induced E.M.F. He dogmatically asserts that there is such a change, and, after devoting a paragraph or two to Mr. Voice, he describes an experiment to show that the number of lines passing through a circuit in an analogous case does change. What, may I ask, has the line "O C" in his sketch to do with the circuit? In which direction is the current there? And how does he apply such reasoning to the Forbes armature, which gives off current all round its perimeter, and is all circuit? Let him show us a real circuit in such a case in which the number of lines does not remain a constant quantity, in which the number of lines entering is not balanced by the number departing.

In the last three but one paragraphs of his letter he sets forth an experiment designed to ascertain whether the lines of force revolve in the manner I suggested. The result, I fear, would not settle the question. A needle situated as described will, of course, assume a position of equilibrium when all is stationary, and will not have that equilibrium disturbed by the rotation of the lines, unless the conditions are such as to allow a current to be produced within the needle's mass, for otherwise there is no reaction. The needle is situated in an invariable field, and the lines which traverse it are balanced in their attractions, the needle's poles attracting the lines approaching them with exactly the same force on one hand as the lines leaving them on the other.

I must accuse Mr. Scattergood of hair-splitting. I fully explained in my last letter what I understand by the term "magnetism" (which I often use, to save waste of breath, in preference to the term "magnetic force").

In the same paragraph I am represented as talking of "force possessing inertia." What I did say was, "may we regard" what he calls the magnetic force "as possessing infinite inertia with respect to rotation about the magnetic axis?" I will not, however, say—since Mr. Scattergood opens that question—that force does not possess inertia; it all depends. I know that force is sometimes inertia, but I do not make bold to offer an opinion what inertia is after that. There is a very good chance for Mr. Scattergood to perpetuate his name if he can tell the world what force is and what it is not. There is more in this than appears on the surface, and if he is sufficiently interested he might profitably turn to a correspondence on the laws of motion which appeared in *The Engineer* in the early part of 1885.

Now, Sir, I have sought information, which no one has been able to give me, and I have taken the liberty to suggest that the lines of force in the Forbes dynamo were only prevented from rotating as fast as the armature by a retarding force due to the generation of Foucault currents in the mass of the field-magnet and surrounding conductors. I have seen nothing in this correspondence to induce me to alter that view, but in thinking over the matter again it has struck me that the E.M.F.'s which would be set up in the field iron, &c., probably balance each other—that, in other words, there is no path open to currents.



Thus, suppose the figure to represent a longitudinal section through the axis of a Forbes machine. The dotted lines L L show the configuration of the lines of force which encircle the exciting coil, and lie in planes which intersect at the axis of the machine. Take *any* line *c d* within the mass of the field-magnet drawn outwards from the exciting coil. Now, suppose the armature to revolve and to drive with it the lines of force, an E.M.F. is at once produced on the line *c d* by the movement of the lines of force across it; but no current can circulate, as I take it, because the return path from the extremities *c* and *d* would necessarily be cut by the same

Digitized by Google

number of rotating lines as *c d*, and a current would therefore be impossible, unless, indeed, it be supposed that a current flows back, so to speak, through the medium of those molecules which are not at any given moment occupied in the production of the E.M.F., for it may be presumed that only a portion of the matter is magnetically polarised unless there be absolute saturation. But if this be true, heating effects should be observable, and it would be interesting to know if heating has been observed under such circumstances. The question whether the molecular movements implied by the motion of the lines of force through such a mass—even if they do not produce an evident current—is not attended by the development of heat is, I believe, unsettled; but, assuming that there is a degree of molecular friction entailed, then undoubtedly the lines would encounter a corresponding degree of resistance.

Returning now to the figure, suppose that we have contacts arranged to bear against the points *c* and *d*, and connected by a conductor which revolves along with the lines of force, then since this conductor is not cut by these lines the potential at *c* and *d* will drive a current through the circuit. Similarly, if we suppose the armature to revolve through the lines of force without the collecting contacts being applied, we have nothing more than E.M.F. induced in it; but as soon as the sliding contacts are applied about the armature's perimeter and at its centre so as complete the circuit through a fixed conductor, as in actual practice, then a path is opened for a current. If the lines of force are driven round with the armature they must necessarily cut through the stationary conductor in the opposite direction to that in which they cut or tend to cut through the armature, so that the same E.M.F. will drive a current through the circuit whether the lines go round with the armature so as to cut the stationary conductor only, whether the lines remain stationary so as to cut the armature only, or whether the truth lies between the two. It is no matter, therefore, whether the lines are partly driven round with the armature contrary to what I at first supposed.

The ordinary rule, reiterated by Mr. Scattergood, that "no induced E.M.F." (much less current) "is possible without a change in the number of lines embraced by a circuit," is not applicable to this dynamo. That rule is only generally convenient because the rate at which lines enter or leave a circuit is an index of the number of lines which traverse the conductor composing it in the direction necessary to produce current.—Yours, &c.,

R. SNOWDON.

Staveley Ironworks, August 8, 1887.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I find Mr. Voice very anxious to prove that the pivot of the machine in question will not or practically will not be cut by any lines of force. Well, assume for argument's sake it is not cut by any lines, what then? The difficulty, as originally stated, was, how could current be produced in two conductors leading radially out of the field, as the inductive action being in the same direction in each they would naturally have an equal and contra E.M.F. when completed in circuit? And I then endeavoured to show that the E.M.F. induced at each disc of the machine as originally drawn would differ, inasmuch as these discs were situated in different positions of the field. Mr. Voice then stated he could get one of his conductors out of the field without being cut by any lines of force; but I have not to this moment been able to discover what this goes to prove or disprove.

As it appears that the explanation I have previously given of the cause of current in a disc machine has been imperfectly understood I will here repeat it; but previously to so doing I will assume that we are agreed as to the necessity of cutting lines of force, and that the E.M.F. of a conductor is dependent on the number of lines of force it cuts in a given time; or, otherwise expressed, with constant velocity the E.M.F. will be proportional to the density, and likewise with constant density the E.M.F. will be proportional to the velocity. In fact, if we substitute for velocity the temperature or heat energy applied to a gas, and for E.M.F. the pressure produced, we shall find that Marriotte's law is quite applicable.

Below I have given two diagrams. No. 1 represents in principle one of Faraday's experiments mentioned by De la Rive. The disc shown is of brass, and is insulated from the magnet, the current being taken off by the two conductors A and B. The disc I treat simply as a conductor, neutral to the action of the lines of force, inasmuch as it revolves with them. Now, the velocity of cutting varies radially throughout either of the conductors A or B, as also inversely the density, and as they vary in the same relative proportions—that is, as the squares of the radial distance—the same E.M.F. will be induced at any point along either of these conductors.

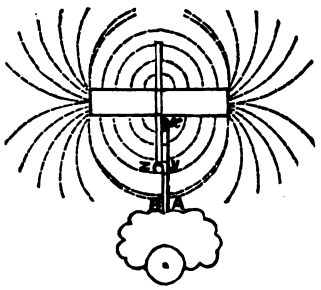


Diagram No. 1.

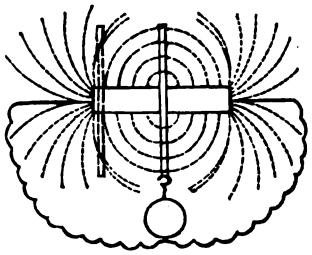

Diagram No. 2

All, then, that we have to consider is the simple fact that A has an additional cutting through the length extending from *y* to *x*, and hence, although the portion *z* B and *y* A have an equal and opposed force induced, we still have the excess of E.M.F. in *x y* to spare, which in this case is the true course of the current. No. 2 shows Weber's machine, in which the disc is in electrical connection with the magnet. Here it is evident that the conductor at the centre could cut more lines of force than the pivot at the end, and that a higher E.M.F. would be generated in the former. If, however, the disc be placed at the end as shown dotted I would expect a reduction in E.M.F., and I cannot see how Weber could get otherwise when he states that "the absolute effect was considerably less," especially as the resistance may be reduced by coupling the disc to the near end of the magnet.

This diagram will also serve to show how Mr. Voice obtained current off the two discs of his first machine. If I remember rightly, Mr. Voice was of opinion that the two discs would be each under the same degree of inductive influence.

Will Mr. Voice, then, please explain on his own theory how current can be produced in two discs under the same inductive influence when revolving on the same magnetic axis?

I believe I am correct in stating that there are those who hold that a conductor must move in a field of varying influence. I do not myself see the necessity, but it is a point I should not like to be too dogmatic about.

It seems to me that as all machines have by necessity of construction varying fields, we have no disproof of the contrary assumption. The fact of inducing different degrees of potential along the line of the conductor cannot determine the directive action of the current, as is seen in the case of disc machines, for on this theory we would expect the directive action to be the result of a flow, so to speak, from a point of high potential to that of a lower potential, whereas in a disc machine the contrary may take place. The direction, then, of a current would appear to be determined by the action of the molecules themselves. If the two conductors in diagram No. 1 were taken up vertically and approximately in the same plane as shown, they would be, as previously stated, under a uniform inductive influence, and here would be a proof that a varying inductive influence on a conductor is not necessary.

Of course, by this theory the necessary molecular oscillations are ascribed to the conduct of the field itself; it is assumed that its structure, be it that of concentric waves or a bundle of parallel vortices, is such as to impart these oscillations when cut by a conductor in the orthodox fashion. I cannot see how the fact of the current being double when both pivots are coupled to the circuit in any way proves or disproves Mr. Voice's independent field theory, and I purposely avoided referring to this again, as it seemed to me to

Digitized by Google

be only waste of time and space. Even if it was important, we are informed of a fact without any data whatever as to galvanometer resistance, &c. Of course I should expect the result to be two if there was no galvanometer resistance, but Mr. Voice seems to think that parallel paths give double resistance. I appear to have misunderstood Mr. Voice's question about the Gramme ring. He now states that "when a mass of iron is moved in a magnetic field currents are produced in it transversely to the direction of such movement by reason of conductivity, and the mechanical resistance is caused, not by the difficulty of the iron passing through the lines of force, but by another kind of force—electricity—being formed in it, which acts on the magnetism." May I ask how a quality such as conductivity can in itself be a cause of action? We might with equal truth say a corkscrew will draw a cork because it is of suitable form, and therefore no force is necessary.

Mr. Voice touches on a difficult subject when he refers to the free action of a non-conductor in a magnetic field. The quality conductivity is apparently that which determines the efficiency of induction or the quantity of mechanical force that will be transformed into electrical action. If, then, the resistance of the field reacts on the molecular constitution of the conductor, how is it that non-conductors are not subjected to the same action? The only satisfactory answer to this question is that the molecular porosity of a non-conductor is such that the ether has free action through its interstices. To conceive such phenomena possible when the body is in motion, we must assume the atoms of the ether field to possess an infinitely higher velocity than any mechanical movement we can impart, and hence with a given molecular porosity the transmissive action would be almost as good when the body is in motion as when at rest.

We might then expect bodies of a dense nature such as copper to obstruct when in motion the due action of the magnetic field, and thereby produce current. The subject, of course, is fraught with many difficulties, and is of a very speculative nature, and I wish it to be understood that the action I have endeavoured to trace above is that of a body cutting the lines of force only, and is not intended to apply to its behaviour when moved parallel to their course.

As Mr. Voice still believes in an independent field, I will ask him to inform me how it is that current is produced in a copper disc revolving between two magnetic poles, the periphery of the disc being below the axis of the poles? If the magnetic field between these poles were free to move around its axis, where would be the resistance to the movement of the disc?

But Mr. Voice must first clearly understand that where force is applied resistance must be opposed if work is to be done. Again, I might point to the fact that a polarised ray of light travelling along the axis of a stationary magnetic field receives a spiral twist. What is the action that gives it this twist? Clearly the field. How, then, can the field produce a rotating strain if it were perfectly free to revolve?

There appears to me to be one feature in the action of a Gramme armature that gives some colouring to Mr. Voice's theory. I refer to the reflex field produced by the current passing through the coils of the bobbin. Such a field would have its axis lie between the two brushes, and it would seem at first sight that as these brushes are fixed and the position of the field secured we have a case where the tangible part of an electro-magnet is revolving through its own field. But it would be more correct to say that the coils could not pass through lines that are produced by their agency, and that hence the lines of force of this field are actually revolving with the coils, although the total effect as a whole is that of a field having its poles situated at the brushes.

Mr. Voice, I notice, repeats an isolated sentence of mine, "Why have a core at all?" and proceeds to argue as though I were ignorant of the use of an iron core in an electro-magnet. If he will please re-read my letter he will see I was referring only to a permanent magnet, and the question was asked in conjunction with his theory that such a magnet would possess an independent field. The term core was not perfectly correct, but I used it to distinguish between the magnet as a whole and the steel constituting its material part.

I do not clearly follow Mr. Scattergood's explanation of the production of current in the machine under discussion, and I do not think he is correct in defining a magnetic field. As a field of force only there is something more material about it. Force is not conceivable as a quality in itself, *i.e.*, independent of mass; and it is the ether atoms or molecules under the influence of force that constitute, in my opinion, a magnetic field.—Yours, &c.,

N. G. THOMPSON.

4; Queen Victoria-street, E.C., Aug. 10, 1887.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XLIV.

BY OLIVER HEAVISIDE.

Any number of non-distortional circuits radiating from a centre, operated upon simultaneously. Effect of intermediate resistance: transmitted and reflected waves. Effect of a continuous distribution of resistance. Perfectly insulated circuit of no resistance. Genesis and development of a tail due to resistance. Equation of a tail in a perfectly insulated circuit.

If the ends of the two conductors of a non-distortional circuit at its termination at A be caused to have a difference of potential V_0, varying in any manner with the time, and if there be an absorbing resistance inserted at the other termination B, we know that the impedance of the circuit to V_0 is Lv, a constant, at every moment, so that the current there is V_0/Lv. We also know how the potential-difference and current are transmitted, attenuating to $V_0\rho$ and $V_0\rho/Lv$ on arrival at B.

If there be a second non-distortional circuit starting from A, and we simultaneously maintain the same difference of potential V_0 on it, we know what happens on it, viz., as above described, merely changing, if necessary, the values of ρ and Lv. That is, if the circuit be not of the same type as the first one, and of the same length, we require to use different values of ρ and Lv.

This obviously leads to the working of any number of non-distortional circuits in parallel by a common impressed force at A. Call the wires of a circuit the right and the left wires, merely for distinction. Join all the right wires to one terminal A_1, and all the left wires to another, A_2, and then maintain a difference of potential V_0 between A_1 and A_2. Then, provided every circuit has its proper absorbing resistance at the distant end, we know what happens. The reciprocal of the sum of the impedances of the various circuits is the effective impedance to V_0. Next, V_0 divided by the effective impedance (say I), is the total current. Finally the total current divides amongst the circuits in the inverse ratio of their impedances. The current at the distant end B of any circuit is the current entering it at A at the time l/v earlier, multiplied by the attenuation-factor ρ of the circuit. I do not write out the equations, as the descriprion is fully equivalent.

In order that V_0 should be strictly proportional to an impressed force e in the branch joining the two common terminals A_1, A_2 of the circuits, it is necessary that it should be a mere resistance, which may have any value. Let it be R_0; then, R_0 added to the previous effective impedance to V_0, is the impedance to e; so that the total current is $e/(R_0+I)$, and the value of V_0 is $eI/(R_0+I)$. In practice it is not possible to fully realise this simplicity. Supposing, for instance, the secondary of the transformer, in the circuit of whose primary a microphone is placed, be joined across the common terminals of the circuits. Even if the circuits be non-distortional, we see that there must be terminal distortion, or V_0 will not vary as it should for the accurate transmission of speech. There are several causes of distortion here. At the distant end, one cause of further distortion will be the inductance of the receiving telephone, and an additional and very important one will be the mechanical troubles that will prevent the disc from copying accurately in its motions, the magnetic force variations.

After this example of a complex arrangement of circuits admitting of simple treatment, let us return to a single circuit. Examine the effect of inserting any resistance r intermediately.

Digitized by Google

This should be put half in each wire, if the circuit consist of a pair of equal wires, to prevent interferences. Let there be a wave travelling from left to right towards r. Let V_1, V_2, V_3 be the potential-differences in corresponding portions of the incident, reflected, and transmitted waves, so that, at a certain moment, they are coincident, viz. at r itself, where let V be the actual potential-difference on the left side of r. Then we have

$$\left.\begin{array}{ll} V_1 = LvC_1, & V_2 = -LvC_2, \quad V_3 = LvC_3, \\ V_1 + V_2 = V = rC_3 + V_3, & C_1 + C_2 = C_3. \end{array}\right\} \quad (36d).$$

These are the full connections. From them,

$$\frac{V_2}{V_1} = \frac{r}{r+2Lv}, \quad \frac{V_3}{V_1} = \frac{2Lv}{r+2Lv} = \sigma \text{ say.} \quad . \quad (37d).$$

Particularly notice that

$$V_1 = V_2 + V_3, \quad . \quad . \quad . \quad . \quad . \quad (38d),$$

as this is an important property. Every element of electrification in the incident wave arriving at the resistance is split into two (without any loss), one part σV_1 (in terms of potential-difference) is transmitted, the remainder is reflected.

As we have, by (37d)

$$r = 2Lv\,(\sigma^{-1} - 1), \quad . \quad . \quad . \quad . \quad (39d).$$

we see that if 1 per cent. of the incident wave be reflected, and 99 per cent. transmitted, we require $r = \frac{2}{99}Lv$. If 10 per cent. be reflected and 90 per cent. transmitted, then $r = \frac{2}{9}Lv$.

There is no transmitted wave if r be infinite. Half is transmitted and half reflected when $r = 2Lv$.

There is always a loss of energy by this division of the charge, which is accounted for by the Joule heat in the resistance. This is rC_3^2 per second; and since a wave of unit length takes v^{-1} second to pass, rC_3^2/v is the loss of energy per unit length of the incident wave, which loss, if added to the sum of the energies in the reflected and transmitted waves, makes up the energy per unit length in the incident. Another expression for the loss of energy is given by

$$\frac{rC_3^2}{v} = \frac{4V_1^2 r}{v(r+2Lv)^2} \quad . \quad . \quad . \quad . \quad . \quad (40d).$$

There is the greatest possible loss of energy when $r = 2Lv$, making $\sigma = \frac{1}{2}$, and the loss $= \frac{1}{2}SV_1^2$. That is, when the intermediate resistance is twice the critical, and the incident wave is consequently half transmitted, half reflected, then half the energy is wasted in the resistance. As the resistance is further increased, the transmitted wave gets smaller, and when it is infinite, we fall back upon the case already considered of total reflection without reversal of electrification or loss of energy.

If we have the absorbing resistance at A and at B, and any resistance r at an intermediate point C, we have a very simple result when any waves are sent from A to B, or from B to A. Suppose e acts at A, and that ρ_1, ρ_2 are the attenuations in the two sections AC and CB. Then $V_1 = e$ at A becomes $V_1 = e\rho_1$ on arriving at C. The reflected wave is $V_2 = e\rho_1(1-\sigma)$, where σ is given by (37d). On arrival at A it is absorbed, so there is an end of it. The transmitted wave at C is $V_3 = e\rho_1\sigma$, which attenuates to $V_3 = e\rho_1\sigma\rho_2 = e\sigma\rho$ on arrival at B, where it is absorbed. The last equation therefore gives the potential difference at B in terms of that at A at the time l/v earlier. In the first section of the circuit V is the sum of two oppositely travelling waves, and the current is their difference divided by Lv; but in the second section there is but one wave.

We are also able to solve by algebra alone the following problem. Given a non-distortional circuit with any terminal resistances and any intermediate resistances at different places, find the effect due to a steady impressed force inserted anywhere in the circuit (half in each wire, pointing oppositely in space, to avoid interferences). For we have the circuit divided into sections, for each of which the attenuation is known (*i.e.* $\rho_1 = \epsilon^{-Rx_1/Lv}$ in a section of length x_1); we also know the transforming factors of the terminal resistances (ρ_0 and ρ_1 of the last section); and we also now know the factors σ and $1-\sigma$ for any intermediate resistance, by which we express how a wave divides there. So, starting when e is first put on, with the initial waves $\frac{1}{2}e$ to the right, and $\frac{1}{2}e$ to the left, we can follow the whole course of events until we arrive (asymptotically) at the steady state. But it is no part of my intention to enter into the details, as nothing new would be contained therein.

But the effect of a great number of equal intermediate resistances equidistantly situated is of importance. Let ρ_1 be the attenuation due to the circuit between two consecutive resistances, and σ the attenuation due to each resistance, that is, the attenuation of the transmitted wave. Let an isolated disturbance go from A to B. If it be initially V_0, it becomes $V_0\rho_1\sigma$ one section further on, $V_0(\rho_1\sigma)^2$ after another section is passed, and so on, becoming $V_0\rho_1{}^n\sigma^n$ after passing n sections. If these n sections make up the whole circuit, then $\rho_1{}^n = \rho$, the attenuation in the circuit due to itself only, as before, so that in passing through the circuit, V_0 is attenuated to $V_0\rho\sigma^n$.

Now let the sum of the inserted resistances be $nr = R_1$. Increase n indefinitely, whilst reducing r in the same ratio, thus keeping R_1 constant. In the limit the resistance R_1 becomes uniformly distributed in the circuit, and the attenuation due to it becomes, by (37d),

$$\sigma^n = (1 + R_1/2Lvn)^{-n}, \quad \text{with } n = \infty,$$
$$= \epsilon^{-R_1/2Lv} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (41d)$$

Observe the presence of the 2. From this we may conclude certainly (as will be shown later), that if this uniformly distributed resistance R_1, in addition to the original Rl, be accompanied by uniformly distributed leakage-conductance of total amount K_1, such that $R_1/L = K_1/S$, the attenuation due to both R_1 and K_1 together is expressed by the square of (41d). For what we do is to make the circuit non-distortional again, by the additional leakage to compensate the additional resistance of the wires.

But the simplest way of viewing the matter is to start with a perfectly insulated circuit of no resistance. This is a non-distortional circuit, of course, since it obeys the law $R/L = K/S$. The only difference from a real non-distortional circuit is that there is no attenuation at all. All the preceding results therefore apply, remembering that $\rho = 1$, or any waves are transmitted, not merely undistorted, but also unattenuated. They are, in fact, purely plane waves of light (very long waves practically) travelling through a perfectly non-conducting dielectric. They are merely guided through space in a definite manner by the conductors, imagined to have no resistance, so that, to use a very gross simile, the electricity slips along like greased lightning. There is no penetration of the electromagnetic field into the conductors, but purely surface conduction, where we may use the word in a popular sense (conduct = to lead). Some curious consequences of the absence of resistance I will notice later; at present I may observe that owing to the relative simplicity produced by the absence of attenuation, the imaginary circuit of no resistance is useful for investigating the effect of inserting resistances, bridges, &c., and the action of a real non-distortional circuit itself.

Thus, imagine an isolated charge moving from left to right in the circuit of no resistance. Introduce anywhere a resistance r; this will cause an attenuation from 1 to σ in passing the resistance (equation (37d)) and the remainder $1-\sigma$ will be reflected back. Next let there be a great number of equidistant small equal resistances; every one of these will attenuate in the ratio $1 : \sigma$, and throw back the fraction $1-\sigma$. The result is that the original isolated charge, as it travels along, becomes a nucleus with a long slender tail behind it; the nucleus travelling forward at speed v and attenuating in the manner described; the tail stretching out the other way at speed v. If these isolated resistances be packed together very closely, and be each very small, we approximate to the effect of continuously distributed resistance, that is, the resistance of the wires in a real circuit. In the limit, the result is, by (41d), that the nucleus, if originally represented by $V_0 a$, that is, the potential-difference V_0 through the very small distance a, with current to match viz., V_0/Lv through the same distance a, and therefore moving entirely to the right at that particular moment, becomes attenuated to

$$V_0 a.\epsilon^{-Rx/2Lv} = \epsilon^{-R/2L}.V_0 a \quad . \quad . \quad . \quad (42d),$$

Digitized by Google

in the time $t = x/v$, during which it has moved through the distance x to the right, if the resistance per unit length be R.

Since there is here no leakage, the rest of the original charge must be in the tail. The amount of electricity in the tail is therefore

$$S \times V_0 a(1 - \epsilon^{-Rt/2L}), \quad . \quad . \quad . \quad . \quad (43d),$$

when the circuit is perfectly insulated. The length of the tail is $2x$, half being to the right and half to the left of the position of the original isolated charge, it being of course supposed that neither the head nor the tail has suffered any extraneous operations, as terminal reflections, &c.

In a similar manner, if initially the isolated charge SV_0a be without current, so that it would, were there no resistance, at once divide into equal halves, travelling in opposite directions without attenuation, what will really happen will be an immediate splitting into halves and separation of two nuclei, travelling in opposite directions at speed v, attenuating as they progress according to (42d), and joined by a band, consisting of the two tails superimposed. The equation of this double-tail is

$$V = \tfrac{1}{2}V_0 a \,.\, \epsilon^{-Rt/2L} \,.\, \frac{1}{v}\left(\frac{R}{2L} + \frac{d}{dt}\right) J_0 \left\{ \frac{R}{2Lv}(x^2 - v^2t^2)^{\frac{1}{2}} \right\}, \; . \; (44d)$$

in a finite form (as usually understood, by a convention that a solution in terms of a sine or J_0 function, &c., is in a finite form, though it is really an infinite series), true from $x = -vt$ to $x = +vt$, it being supposed that the origin of x was the original position of the charge. At the ends of this tail the two nuclei, each represented by

$$V = \tfrac{1}{2}V_0 \epsilon^{-Rt/2L} \quad . \quad . \quad . \quad . \quad . \quad (45d)$$

through the very small distance a, must be placed, to make up the complete solution. I shall later illustrate this graphically, and also explain the other kind of tail.

(*To be continued.*)

LITERATURE.

Electro-Deposition: a Practical Treatise on the Electrolysis of Gold, Silver, Copper, Nickel, and other Metals and Alloys, &c., with several Chapters on Electro-Metallurgy. By ALEXANDER WATT. Second Edition, revised and corrected. [London: Crosby Lockwood and Co., 1887.]

This book is manifestly written by a practical electro-plater, or by one who has spent a large period of time in manufactories of electro-plate. It is essentially and conspicuously a "rule of thumb" manual, and contains a very large amount of such information as comes within the capacities of the ordinary British workman. With great industry the author has collected a multitude of details respecting electro-plate workshop manipulation, the preparation and treatment of nearly all kinds of objects requiring to be coated electrolytically with metal, and especially respecting the electro-plating of them with nickel; and the latter appears to be the department with which he is the most familiar. The subject matter of the book is conveniently divided into chapters of moderate dimensions, and the contents of each paragraph are distinctly indicated by bold headings. The printer's errors are not numerous, and, with some exceptions, the information generally in the book is fairly up to date. The index is copious, and extends to about fifty pages.

The author is conscious of the necessity and advantage of theoretical knowledge to the working electro-depositor, for in the preface of his book he mentions "the chemical and electrical principles of electrolysis, the knowledge of which is essential to those who would practise the art of electro-deposition with economy and success;" and on page 80 he says:—"It is necessary, in the present advanced state of electrical science, that both the student and the practical operator should be acquainted with the principles and laws which govern the development of electricity—that *force* or *power* with which he has to deal in all electrolytic operations."

Notwithstanding these admissions of the necessity of fundamental knowledge of chemistry and electricity as relating to electro-deposition of metals, the book is seriously deficient in the chemical, the thermo-chemical, the electro chemical, and the voltaic principles of the subject. From beginning to end of the work the chemical, voltaic, and electro-chemical equivalents of the elementary substances, and their respective amounts of thermal energy, are not given or explained. On page 72 it is stated that "The decomposing effects produced by the voltaic current in different electrolytes are precisely in accordance with the *atomic-weights* or *chemical-equivalents* (which see) of the substances electrolysed." "For example, the same amount of electricity that would reduce 56 parts of iron from its solution to the metallic state would reduce 207 parts of lead or 108 parts of silver." But the "*equivalents*" referred to are not given anywhere in the book. On page 513 there is a table of atomic-weights of the chemical elements, but not of equivalents, nor is the reader informed that the two are in many cases widely different from each other; the only sign given that there exists any difference between *chemical-equivalent* and *atomic-weight* is in a foot-note to the table on page 513, saying "the combining-*weight* of oxygen is 8." Further, "the same amount of electricity that would reduce 108 parts of silver from its solution to the metallic state" would *not* "reduce 56 parts of iron," nor would it "reduce 207 parts of lead;" these proportions are the *atomic-weights* and *not* the *chemical-equivalents*; either the amount given of silver is only half the proper quantity, or those of iron and lead are double the correct amounts. In Chapters V. and VI., relating to the "Theory of Electrolysis," and "Electrical Theories in their Relation to the Electro-deposition of Metals," nothing is stated respecting the important relations of electrolysis to the amounts of heat evolved and absorbed by the chemical changes continually occurring at the electrodes in the electrolysis vessels, and at the surfaces of the battery plates in the voltaic cells, and upon which depend the quantities of electric energy which must be supplied in order to produce electrolysis; nor is any table given of the amounts of heat evolved and absorbed in chemical and electro-chemical actions.

In consequence of the omission of the chemical equivalents of the elements, and the absence of any correct technical rule based upon them, the depositor is not enabled to calculate what quantities of the respective acids, bases, or salts, he must take in order to make or correct his various solutions, but must trust to some "rule of thumb" method. He is not shown the way to calculate how much acid or zinc must be consumed in his voltaic battery in order to deposit a given weight of silver in the electrolytic vat; nor is he enabled to ascertain the relative amounts of silver, copper, gold, and other substances which would be deposited by the same amount of electric current, whether obtained from a dynamo electric machine or a voltaic battery. In all cases where the electro-depositor would have to calculate the cost of depositing different metals—especially in cases outside those of his ordinary experience, and still more so in those in which high electromotive force is required, as when non-corroded anodes are employed—this deficiency of knowledge respecting chemical equivalents, and especially respecting the amounts of heat evolved and absorbed, and the corresponding quantities of electric energy consumed in electrolytic actions, would be an insuperable obstacle.

The chemical formulæ, also, of the various compounds which are used, or liable to be used, in the art of electro-deposition are almost entirely omitted, similarly with the equivalents and molecular weights of those compounds, including those of the most ordinary substances, such as oil of vitriol, blue vitriol, lime, soda, potash, silver cyanide, potassium cyanide, double chloride of ammonium and nickel, hydrochloric acid, nitric acid, &c.; ditto with regard to the commonest salts of lead, cadmium, zinc, tin, iron, copper, nickel, bismuth, antimony, gold, platinum, silver, sulphates, chlorides, nitrates, &c. Nearly the only exception to these statements is on page 483, where, in speaking of the double sulphate of nickel and ammonium, used for nickel plating, the author states:—"The double salt consists of one atom of sulphate of nickel, one atom of sulphate of ammonium, and eight of water." Had these formulæ been given, they would have assisted the practical electro-depositor in remembering more perfectly the actual chemical composition

Digitized by Google

of the substances used in his calling; they would also have enabled him, in some cases, to ascertain the chemical equivalents of bodies by comparing the formulæ with each other and with the atomic weights of the elements.

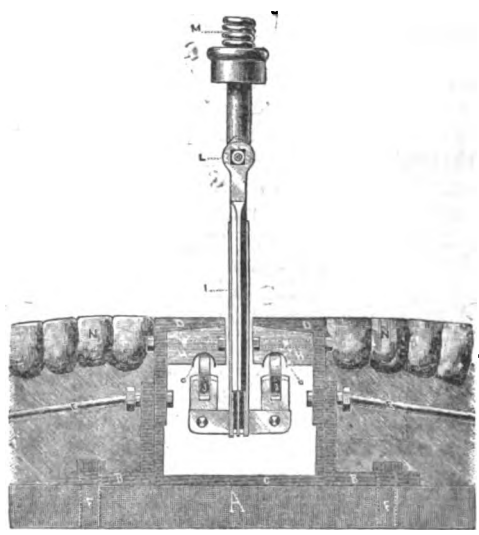
On page 214, the author very correctly remarks, that "the introduction of the electro-gilding art greatly favoured such unscrupulous persons as desired to prey upon the public by selling as gold, electro-gilt articles, which had not a fraction of the precious metal in their composition," and he mentions as an example, the manufacture of an alloy termed "mystery gold," composed of "copper 65·50, platinum 32·02, and silver 2·48;" and says, "it appears that when converted into jewellery the chief aim of the manufacturers is to defraud pawnbrokers, to whom the articles are offered in pledge, and since they readily withstand the nitric acid test the transactions are often successful." In contrast with this, we will now quote a plan recommended by himself on the immediately preceding page (p. 213). Under the heading of "gilding cheap jewellery," he says, "this class of work seldom requires more than a mere *dip* to meet the requirements of the customer; indeed, the prices obtainable for gilding articles of this character will not admit of *gilding* in the proper sense of the term." "The author has found it a very economical plan to use a *copper* anode for gilding work of this description, and by making small additions of chloride of gold when the bath exhibited signs of weakness he has been able to gild a very large number of articles, of a very fine colour, with an infinitesimal amount of the precious metal." "In his experience, although the prices were very low, the result was exceedingly profitable. Against the employment of a copper anode it has been argued that the solution must of necessity become highly impregnated with copper. To which we may reply that we did not find such to be the case in practice." In using this method, recommended by the author, his copper anode undoubtedly did dissolve in the cyanide liquid, the liquid also did become impregnated with copper, and the reason why his solution did not "become highly impregnated with copper" was that after a time the copper was deposited as an alloy with the gold upon the articles as fast as it was dissolved, and in this way produced the "very fine colour," and conduced to the "exceedingly profitable result." In proof of this explanation being the correct one, we refer the reader to page 197, where the author, in his instructions for depositing alloys of gold, and "gilding in various colours," recommends the following method for obtaining a deposit of "red gold:"—"To a solution of cyanide of gold add a small quantity of cyanide of copper solution, and increase the quantity gradually until the required tone is obtained, since an excess of the copper solution would produce a deposit of too *coppery* a hue." These recommendations are given in the same terms in the "second edition, revised and corrected," as in the first edition.

In Chapters XXIX., XXX., and XXXI., on "Electro-Metallurgy," the author has compiled, from various sources, nearly all the information at the time existing respecting the use of electrolysis in the refining of crude metals, especially copper, on a large scale; and the attempted practical application of electrolysis to the economical extraction of metals from metallic matter and from mineral sulphides in their unreduced state. The information contained in those chapters is especially interesting at the present time, in consequence of the rapid extension of the use of electrolysis on a scale of great magnitude to the refining of copper, and its adoption by most of the great copper smelters. This information, especially so far as it relates to other metals than copper, should, however, be cautiously received, because various of the processes described are in a state of trial or development, and are not yet perfected. Six pages in Chapter XXXI. are devoted to a description illustrated by sketches of Cowles's electric smelting furnace, in which, by means of the electric arc between the ends of exceedingly large rods of carbon, aided by the heat of conduction-resistance of a mixture of broken minerals, charcoal, and metals, an excessively high temperature, far exceeding that of any previous furnace, has been obtained, and the oxides of aluminium and silicon reduced to their elementary states to form alloys. But whilst this description is exceedingly interesting, it is a question as to how far the action which takes place in this furnace is really electrolytic, and how far it is merely chemical; the process also, even now, is not completely developed.

Seeing that the book contains so large an amount of workshop information, its title might well have been "Manipulations in Electro-plating, &c." The author has substantially attained his "desire to furnish a comprehensive treatise, embodying all the practical processes and improvements in the art of electro-deposition;" but in consequence of the serious omission of some of the most fundamental principles of the subject, we do not think that he has fully accomplished his object, "to treat the more scientific portion of the work in such a manner that those who are not deeply versed in science may readily comprehend the chemical and electrical principles of electrolysis." Notwithstanding its deficiencies, redundancies, &c., the book will prove of considerable value to electro-platers, jewellers and others, and will be especially welcomed by ordinary working electro-platers.

THE "BIDWELL" ELECTRIC RAILWAY CONDUIT.

It is obvious that the problem of providing mechanical and structural devices for taking off current from a conductor laid in a channel along a tram or railway line is one which admits of an immense number of solutions, and it is probable that every electrical engineer who has to turn his attention in this direction will work out the detail in his own way. At the same time, it cannot be said that the problem of properly protecting a bare wire laid in an open channel along the street is altogether an easy one, nor is it probable that any system at present in operation has yet arrived at the stage of finality. At Blackpool, for instance, on Mr. Holroyd Smith's system, very considerable difficulty has been experienced this summer from the expansion of the conductor, owing to the excessive heat, so much so that recently for several days horse-traction had to be resumed. This difficulty is one, however, which should admit of being easily overcome, and ought, indeed, to have been adequately provided for in the first design.



The Bidwell Electric Railway Conduit.—Transverse Section.

A more serious difficulty is met with in ensuring the complete insulation of the conductor and its protection from mechanical injury or from wilful interference. The former object is, of course, of the highest importance, especially when both positive and negative conductors are enclosed in the same conduit. In our new contemporary, the *Western Electrician*, of Chicago, we find a description of a device which perhaps ensures better protection from external sources of injury than any which has yet come under our notice, and it has also the advantage of enabling the channel to be easily swept and cleared from obstruction. The following is the description given by

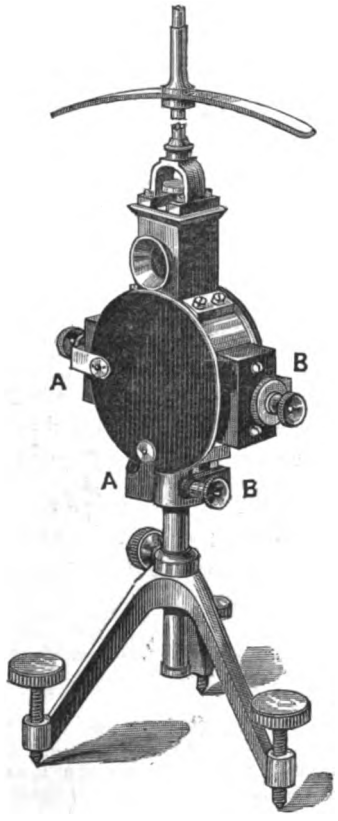
Digitized by Google

our contemporary: "The construction under this system is shown in the accompanying engraving, which represents a transverse section, and consists of the conduit placed between the rails and beneath the surface, 6in. wide and 8in. deep, with a slot or space five-eighths of an inch wide at the surface, running parallel with an opening into the conduit. A represents the cross tie upon which the conductor is placed, NN the pavement; B B angle braces; C lower conduit case; D D upper conduit case; E E stay rods. The electrical conductors G G are concave, and suspended under the surface plates D D, but properly insulated from them by the insulating wood H H. Thus suspended the conductors are placed in a position of perfect security from interference in any manner whatever, and thereby ensure an undisturbed and undiminished current. The electrical contact between the conductors and the motor on the car is made by means of the arm I, supported by the adjusting spring M, which sets in a case in the bottom frame of the car. The arm projects down through the slot into the conduit, and holds in place the contact wheels J J, which run in the concavity of the suspended conductors G G. The spring alluded to above, and the knuckle joint L, adjust and provide for the motion of the car, thus guaranteeing perfect and constant electrical contact without sparking. Both currents, outgoing and return, are provided for by the two conductors, and pass through the arm connection, which is so insulated that they are perfectly separated."

It will thus be seen that any accidental contact with the conductor from the surface is so far rendered impossible as to admit of the use of higher tension than has yet been attempted on lines of this class. The weakest point in the design is probably the employment of rolling contact makers through the spindles of which the current has to pass; but it will, of course, be easy to supplement them with brushes bearing either on the side of the wheels or on the conductors themselves.

NEW INTERCHANGEABLE COIL GALVANOMETER.

We herewith illustrate a new form of galvanometer recently exhibited by Messrs. Nalder Brothers and Co., at the Royal Society and elsewhere. It is specially designed for use when the work is much varied and where several galvanometers of different resistances would be otherwise required.



A New Interchangeable Coil Galvanometer.

The coils are made so that they can be taken out and replaced by others in a few seconds without displacing the magnet needles. Coils of various resistances are supplied as required. They are fixed in ebonite boxes which fit into the body of the instrument, and are secured by copper straps which fit under the terminals as shown in the figure. The lower terminals are insulated from the stand, and joined together, so that the two coils are connected by their lower straps, while their upper ones make connection with the terminals of the instrument. The coils are thus fixed and joined up at the same time without any loose wires.

The mirror is at the top, and works in the square lantern, where it is strongly damped. The fact that the centre of the coil has to accommodate the magnet alone obviates the necessity of a large opening, and allows the wire to be brought nearer to the needle. This form of construction also allows the two halves of the coil to be brought very close together. It will be seen that the stand is of the usual tripod form, but is adjustable for height, which is an obvious advantage. To save space the rod at the top, upon which the controlling magnet slides, is shown broken in the figure.

It only remains to add that in respect of workmanship and finish the instrument fully sustains the deservedly high reputation already attained by the firm of Nalder Brothers and Co. for high class work of this description.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis:—

RECHERCHES SUR LA CONDUCTIBILITE GALVANIQUE DES ELECTROLYTES.

BY SVANTÉ ARRHENIUS.

(*Continued from page 279.*)

§ 7.—Important Case of Double Decomposition.

From the simplified formula indicated above by an "α," one can at once deduce some important propositions. From (2 α), viz.:—

$$\alpha\,\delta\,(1-x)\,(n-x) = x^2\,\beta\,\gamma$$

one finds, by a discussion like that preceding prop. 24, that if one mixes two bodies A B and C D, the bodies A D and C B will also form, and that the more as $\alpha\,\delta/\beta\,\gamma$ is greater.

According to (4 α) [that is, (4) with $p=0$, $q=0$], $\frac{dx}{dn}$ is always positive, so—

(28) *The more one adds a body to a system in equilibrium, the more will the opposite bodies be formed.*

Then if the body is water, and one adds it to a salt, one has immediately the following consequences:—

(29) *Every salt dissolved in water partially splits up into acid and base. The quantity of these products of decomposition is so much more considerable as acid and base are feebler and the quantity of water greater.*

Let α and δ be the coefficients of activity of the salt and water, β and γ the same for acid and base; then in the majority of cases $\alpha\delta$ is enormously smaller than $\beta\gamma$; consequently for small values of n* (in the case of strong acids and strong bases n can without inconvenience rise as high as 10,000) we can neglect the term $\alpha\delta\ (n+1)/(\beta\gamma-\alpha\delta)$ in comparison with the radical, and so—

$$x = \sqrt{\frac{\alpha\,\delta\,n}{\beta\,\gamma-\alpha\,\delta}} \quad \ldots\ldots\ldots \quad (6)$$

If, on the contrary, n is excessively great, one gets—

$$x = 1 \quad \ldots\ldots\ldots \quad (7)$$

These two formulæ indicate that—

(30) *By moderate dilution the amount of salt decomposed is approximately proportional to the square root of the quantity of water used to dissolve it.*

(31) *A salt is completely split up if the water used to dissolve it is infinite.*

What is here said about water is evidently applicable to every other dissolving electrolyte.

On this subject (the decomposition of salts by water) one reads in the work of M. Berthelot (p. 199), "The process of decomposition by water of the salts of feeble acids is not always the same. Sometimes it increases little by little, either indefinitely with each addition of water, or tending towards a certain limit. . . . . Sometimes, on the contrary, the decomposition of a neutral salt is accomplished almost wholly by the first dose of water."

Thus, 1st. The salts of strong acids with strong bases are not decomposed. According to prop. 30 they ought to be. At the same time the example of the previous section shows that the salt $NaNO_3$ is only decomposed ·13 per cent. by 100 equivalents of water. Such quantities cannot

* n means the number of equivalents of added substance—for instance, water—for each equivalent of original substance—*c.g.*, salt.

Digitized by Google

be observed by any thermic means (at least, that M. Berthelot employed). This is the reason for supposing that these salts are not decomposed at all. . . . . On the other hand, the salts of strong acids with feeble bases are notably decomposed by water. Ammoniacal salts behave in this manner. In M. Berthelot's work there are a crowd of examples.

2nd. Salts of feeble acids are notably decomposed. For example, ammonic borate is decomposed by 100 equivalents of water 59 6 per cent. Such quantities are well marked by thermal actions. Nevertheless, from what we have just said the decomposition ought to be illimitable. The reason why M. Berthelot in certain cases has only found a limited decomposition is probably because his thermal experiments did not permit the employment of more than 1,000 equivalents of water, and because the decomposition is from the beginning proportional to the square root of the quantity of water added (later still less); whence the first dose of water has an effect equal to that of the three following doses, &c.

3rd. As for salts which are almost wholly decomposed by the first addition of water, they are those for which $\beta\gamma$ is less than $\alpha\delta$ (alcoholates, for example). Concerning these salts we have already said enough. [Then follow a physiological application of law (29), and a reply to some feeble objections to the Williamson-Clausius hypothesis.]

§ 8.—Systems more Complex.

In general the case in which four electrolytes alone establish a chemical equilibrium is rather rare. The most frequent case is that of six or nine electrolytes acting on one another. Nevertheless, it is not difficult to establish general equations for a system of $n\nu$ electrolytes combined of ν cations and n anions. Let them be the following:—

$$\mathrm{I}_1\,\mathrm{J}_1,\ \mathrm{I}_1\,\mathrm{J}_2\ .\ .\ .\ .\ \mathrm{I}_1\,\mathrm{J}_n\ ;\ \mathrm{I}_2\,\mathrm{J}_1,\ \mathrm{I}_2\,\mathrm{J}_2\ .\ .\ .\ .\ \mathrm{I}_2\,\mathrm{J}_n\ ;\ .\ .\ .$$
$$\mathrm{I}_n\ \mathrm{J}_1\ .\ .\ .\ .\ \mathrm{I}_n\ \mathrm{J}_n\ ;$$

with the respective coefficients of activity—

$$a_{11}\,a_{12}\ .\ .\ .\ a_{1n}\ ;\ a_{21}\ .\ .\ .\ a_{2n}\ ;\ .\ .\ .\ ;\ a_{\nu 1}\ .\ .\ a_{\nu n}.$$

Moreover, let the original number of equivalents in the solution be similarly—

$$m_{11}\ .\ .\ .\ .\ m_{1n}\ ;\ .\ .\ .\ .\ ;\ m_{\nu 1}\ .\ .\ .\ .\ m_{\nu n},$$

and the extra number formed at the end of the process—

$$x_{11}\ .\ .\ .\ x_{1n}\ ;\ .\ .\ .\ .\ ;\ x_{\nu 1}\ .\ .\ .\ x_{\nu n}.$$

Further, let us call the quantity—

$$a_{ij}\,(m_{ij}+x_{ij})=r_{ij}$$

the *active mass* of the electrolyte $\mathrm{I}_i\,\mathrm{J}_j$.

Then, in the same manner as in § 6 above, we find a set of equations analogous to (1) and (2), and they take this form:—

$$r_{ij}\ .\ \sum_{i=1}^{i=\nu}\sum_{j=1}^{j=n} r_{ij} \;=\; \sum_{i=1}^{i=\nu} r_{ij}\ .\ \sum_{j=1}^{j=n} r_{ij}.$$

These equations may be written—

$$\frac{(r)}{\Sigma_{(j)}(r)}=\frac{\Sigma_{(i)}(r)}{\Sigma_{(i)}\Sigma_{(j)}(r)}=\text{constants as regards } i;$$

that is,

$$\frac{r_{1j}}{\Sigma r_{1j}}=\frac{r_{2j}}{\Sigma r_{2j}}=\ .\ .\ .=\frac{r_{\nu j}}{\Sigma r_{\nu j}},$$

which we may split up into—

$$\frac{r_{1j}}{r_{2j}}=\frac{\Sigma r_{1j}}{\Sigma r_{2j}}=\text{const.}\ ;\ \frac{r_{2j}}{r_{3j}}=\text{const.}\ ;\ .\ .\ .\ \frac{r_{(\nu-1)j}}{r_{\nu j}}=\text{const.}$$

And so finally we write down—

$$\left.\begin{array}{llll}
\dfrac{r_{11}}{r_{21}}=\dfrac{r_{12}}{r_{22}}=\dfrac{r_{13}}{r_{23}}= & .\ .\ . & \dfrac{r_{1n}}{r_{2n}} \\
\dfrac{r_{21}}{r_{31}}=\dfrac{r_{22}}{r_{32}}=\dfrac{r_{23}}{r_{33}}= & .\ .\ . & \dfrac{r_{2n}}{r_{3n}} \\
\ .\ .\ .\ .\ .\ .\ . & & \\
\ .\ .\ .\ .\ .\ .\ . & & \\
\dfrac{r_{(\nu-1)1}}{r_{\nu 1}}=\dfrac{r_{(\nu-1)2}}{r_{\nu 2}}= & .\ . & \dfrac{r_{(\nu-1)n}}{r_{\nu n}}
\end{array}\right\}\ .\ .\ .\ .\ .\ .\ .\ (\mathrm{A})$$

which are $(n-1)(\nu-1)$ independent equations.

But there are $n\nu$ unknown quantities (x_{ij}) to be determined. So it is necessary to have $n+\nu-1$ fresh equations. These are not difficult to get. We notice that the quantity present of each ion, I_i or J_j, is not altered by the reactions. Hence it follows that—

$$\Sigma_{(i}\,x_{ij}=0,\ \text{and}\ \Sigma_{(j)}\,x_{ij}=0.$$

These are $n+\nu$ fresh equations, one more than is required, but one of them is not independent.

Thus we have all the equations necessary for the solution of the problem. The general equation of the system (A) is—

$$\frac{r_{ij}}{r_{i'j}}=\frac{r_{ij'}}{r_{i'j'}},$$

or

$$r_{ij}\,r_{i'j'}=r_{i'j}\,r_{ij'}.$$

This equation contains the following proposition:—

(32) *When equilibrium is established among any number of electrolytes, the product of the active masses of two conjugate electrolytes is equal to the product of the active masses of their two opposites, just as if no other electrolytes were present.*

This extremely simple proposition contains the solution of the general problem—if one mixes a number of electrolytes together in any proportion, what reactions will occur? By a discussion similar to that preceding prop. 24, one recognises easily that—

(33) *Bodies possessing the smallest coefficients of activity are most likely to be formed at the expense of opposite bodies.*

§ 9.—Applications of the foregoing paragraph.

In practice the case which most often presents itself is that of two electrolytes, whose four ions are different, put to react on each other in a slightly active solvent (most commonly water). We will consider some important special cases.

Case 1. The two electrolytes are a very active acid, and the salt of a less active acid. Let the initial quantities be n and 1. If water were not present, the equation of equilibrium would be—

$$(n-x)(1-x)\,\alpha\delta=x^2\beta\gamma\ .\ .\ .\ .\ .\ .\ .\ .\ 2\mathrm{A}$$

But by reason of the presence of water the salts, of which the quantities will be $1-x$ and x, get into equilibrium with the water and their respective acids and bases. So minute quantities are decomposed by the water, and the quantities $1-x$ and x will be a little diminished, especially $1-x$, the salt of the less active acid. Let us write these so reduced quantities—

$$\frac{1-x}{\chi}\ \text{and}\ \frac{x}{\psi}.$$

Similarly the quantity of reacting acids $n-x$ and x will be a little increased, especially the latter. Call the actual quantities—

$$\lambda\,(n-x)\ \text{and}\ \rho x.$$

Calculation indicates that the greatest of the quantities χ and ψ, λ and ρ, does not differ appreciably from 1 unless $\alpha\delta$ is excessively great in comparison with $\beta\gamma$. So, writing $\psi\lambda/\rho\chi=\tau$, we have proved that $\tau=1$ if $\beta\gamma$ is comparable to $\alpha\delta$. If, on the other hand, $\alpha\delta/\beta\gamma$ is very big, τ will differ from unity, but still $\tau\cdot\alpha\delta/\beta\gamma$ will be enormously great, and hence in the equation—

$$(n-x)\,(1-x)\,\frac{\alpha\delta}{\beta\gamma}\,\tau=x^2$$

it is still necessary to suppose x almost equal to n or to 1, whichever is least. The rôle of the water consists in delaying the process a little, and can, from a broad point of view, be neglected. The same can be said of any other solvent of very small "active mass." We are, then, authorised to announce the following proposition:—

(34) *More active acids displace less active acids from solution of their salts.*

This is the proposition which, valid for bases also, is found in § 5 to agree so well with reality.

[To avoid the appearance of verbal obviousness in this statement, we can remember that by "more active" the author means "having a higher molecular conductivity."]

Case 2. Both electrolytes are salts very little decomposable by water. In this case the water may, of course, be neglected, and $\alpha\beta$ nearly equals $\beta\gamma$, so from the equation (2A) it is necessary that x is comparable either to $n-x$ or $1-x$. Thus a sensible partition of the bases among the acids will be effected.

(35) *If two salts, of which the four ions are different, are dissolved in water (or any other solvent), the two other salts possible will form to such degree that their amounts will be comparable to the amounts of the primitive salts, when the four salts are not notably decomposed by the solvent.*

This proposition, very often verified, expresses a general opinion accepted by chemists. (*See* Berthelot.)

Case 3. If, on the other hand, one of the four possible salts—say, that with the coefficient β—is to a high degree decomposable by the solvent (which is the case if it is composed of a feeble acid and a feeble base), but none of the others, an equilibrium will establish itself between this salt, its acid, its base, and the solvent, in such a way that only a certain fraction, $\frac{x}{\rho}$, remains as a salt in the system, of the quantity which would be found if the salt were not decomposed. (2A) takes the form—

$$(n-x)\,(1-x)\,\alpha\delta=\frac{x^2}{\rho}\,\beta\gamma.$$

So x will increase with ρ, that is to say—

(36) *In solutions of two salts, of which one is composed of strong acid and feeble base, the other of feeble acid and strong base, the strong acid unites by preference with the strong base, leaving the feeble base to the feeble acid. This latter salt is naturally in great part decomposed by the solvent.*

This proposition has been experimentally proved by M. Berthelot (p. 712).

Case 4. If two feeble acids have the same base, M. Berthelot believes he has proved that a sensible partition is effected. According to what has just been said, this ought to be a special case of 1, so that if the acids are almost equally strong a partition occurs; if, on the other hand, one of them is much the stronger, it seizes on a portion of base incomparably the larger. The work of M. Berthelot gives examples of both cases. Thus, a partition occurs between hydrocyanic and boric acids; while the phenol of the phenate of potassium is displaced by boracic acid.

(*To be continued.*)

LEGAL INTELLIGENCE.

Edison and Swan Electric Light Company v. Shippey.

On Wednesday last Mr. Arthur Shippey appeared before Mr. Justice Kekewich, in the Chancery Division of the High Court of Justice, to ask him to reconsider his judgment in this action (which was reported in last week's *Electrician*), on the ground that since his lordship had pronounced that judgment certain facts had come to light which had materially altered the position of affairs. If he (Mr. Shippey) had known those facts at the time of the trial he would not have consented to the order being made, and he was quite sure they would have considerably modified his lordship's decision.

His LORDSHIP said that it was a matter beyond his jurisdiction to rehear a case upon which judgment had been pronounced. Mr. Shippey could, however, move for a new trial on the ground of misstatement of facts, but application must be made in that case to the Court of Appeal.

Mr. SHIPPEY then thanked his lordship, and withdrew.

COMPANIES' MEETINGS.

National Telephone Company (Limited).

The seventh annual ordinary general meeting of this Company was held at the offices, No. 11, Queen Victoria-street, on the 5th inst., under the presidency of Colonel R. Raynsford Jackson.

The SECRETARY (Mr. Wm. B. Campbell) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Our report is perhaps shorter than usual, and the necessity for dwelling at length upon it is also perhaps less pressing than on ordinary occasions. When I addressed you last year I pointed out that there had been a growth in the revenue, and that it had reached the sum of £81,500 for the year, including fee messages, and I explained to you that the fee messages formed a new and growing source of revenue. We had for that year received from £800 to £900 from that source, and now those receipts are £1,800 a year, and they are increasing month by month. The total gross revenue of the Company is now £92,337. 2s. 4d., or rather it was so on 30th June, and it is still steadily and satisfactorily increasing. As regards the trunk wires, I think it is desirable that I should call your special attention to the part of the report which refers to them. You will see that last year our mileage of trunk pole lines was 363, and now it is 643, and that our mileage of wires upon them was at that time 1,216, while it is now 1,919. This is a very important fact, because it indicates a valuable additional service given to those who are members of our local exchanges. They have the means of communication over a much wider area than before, and I am happy to say that they seem to appreciate highly the additional advantage so given to them. I may state without any reserve that it is our desire to extend that system much further. We spent over £8,000 upon it last year, and we shall in all probability expend a considerable sum this year. As I explained last year, our Yorkshire system was connected with the Lancashire and Cheshire system by an arrangement with the Lancashire and Cheshire Company. We are now contemplating no less than connecting our Yorkshire system with Birmingham, the Potteries, and the Nottingham district, so that all our English exchanges, excepting those very far north, in West Cumberland, will be in communication with each other. I need not dwell upon the advantages to the community which will be given by the extra facilities to residents in the towns scattered over our large district when they can hold conversation with each other over that extensive area at a moderate rate. The increase of revenue for the year is somewhat over £11,000, and I may mention that it would have been greater had we not felt it desirable to deal with our tariff in Glasgow. When we started our system there we bought up several rival companies with varying tariffs, and we thought about a year ago that the time had come to equalise those tariffs. In the process of equalisation as a matter of course we lost something. For the year that has just passed we received £2,200 less from our old subscribers than we should have done but for the equalisation of the tariffs, and to that extent our revenue for the year was reduced. I am, however, happy to be able to inform our subscribers and you that the gross revenue from Glasgow is about £1,800 more than it was before we made the reduction. You will see upon the reverse of the report that you will be asked to sanction the issue of £150,000 of what I will call debenture stock. I think that seeing this in the report was probably misleading to some of the shareholders as to the intention of the Directors. We have no intention of issuing any of this debenture stock excepting for the purpose of replacing debenture bonds which are now in the possession of the public to the extent of £75,000. The further issue of £75,000 of debentures will be very much delayed, and we do not see any definite period at which there will be any call for it. We have taken power to issue £150,000 when we only really require £75,000, because if ever hereafter it proves to be desirable to issue a further sum of debenture stock it will certainly be in the interest of the Company that that issue should not be second debenture stock; and it is merely to guard against a somewhat remote possibility that we are asking you for power to issue £150,000 instead of only £75,000 of debenture stock. We have no intention, however, of doing anything more than replace the debenture bonds now in the hands of the public. I do not know that it is necessary for me to detain you by dwelling on any other topic. I am happy to say that as regards our relations with all those with whom we have important business—that is, specially with the Post Office and the United Telephone Company—they are as satisfactory as hitherto, and that generally we stand on friendly terms with those who are using our system. He then concluded by formally moving the adoption of the report and accounts.

Mr. WM. ALEXANDER SMITH (a Director, of Glasgow): I have great pleasure in seconding the adoption of the report and accounts for the past year, and in doing so I can only corroborate what has been stated to you by Colonel Jackson in regard to the position of the Company. I am sure it must be a source of gratification to you all that under Colonel Jackson's guidance it has attained the position it now occupies. I will venture to refer to one or two points which I know Colonel Jackson intended to refer to, but which he has not done. I may say, without fear of contradiction, that this Company has always led the way in the adoption of every possible apparatus which would facilitate the services given to the public; and during the past year everything that can tend to increase our revenue, and to give a quicker service to our subscribers, has been adopted by the Company without loss of time. I have further to advert to the fact that during the past year, at a considerable cost, a large portion of the wires has been renewed and reconstructed, the result being, as Col. Jackson has stated, that we are now on the best possible terms with our subscribers; and in proof of the soundness of our methods of construction, I can only allude to the fact that, in a territory extending as far north as Inverness, down to as far south as Birmingham, all the snowstorms last year only cost the Company £600. I have the greatest pleasure in seconding the adoption of the report and accounts for the past year.

Mr. G. E. SMITH (Nottingham), referring to the question of way-leaves, expressed a fear that in some districts the wires had been run, and that afterwards it had been found necessary to put supports, or insulators, on the poles, and that they had been put on without the permission of the owners of the property. At St. Paul's Church, Nottingham, an old church, two insulators were put on, and three holes were made in the lead, leaving one hole. No one ever gave permission for that to be done. He thought it was very detrimental to the interests of the Company to let such a state of things as that go on. The vicar had been ill, and he had promised the revereрd gentleman to bring the matter before the Directors. He knew it was not the desire of the Chairman that that state of things should continue.

Mr. JOHN LEAKE (Manchester) asked if there would be any objection to giving the shareholders, in the profit and loss account, a division of the item "Working expenses for management, operators' wages, office salaries, and charges, £12,688," stating, for instance, the amount of the Directors' fees and the salaries separately?

The CHAIRMAN: I am obliged to Mr. Smith for the remarks he has made, and for bringing this matter prominently before us. We shall do our best to prevent any neglect or disregarding of our orders. It is our desire that our staff should treat householders and all with whom we have to deal with courtesy, and that we should not claim rights over property which we can only exercise properly, morally, and legally, with the consent of the proprietors or the occupiers; and representations shall be made to Nottingham on the subject. I trust that the particular point which Mr. Smith has referred to will be attended to at once, and that there will be no occasion for complaint again. As to the query of Mr. Leake, I beg to say that hereafter we shall have no objection to make a further subdivision of the items he referred to. He specially mentioned the Directors' fees—they are £1,000 a year. We do not wish to have any reservation, but to give all the information that is thought desirable and that is advantageous to the Company and to our shareholders to give.

The motion was then carried unanimously.

The CHAIRMAN next moved, and Mr. PETER GARNETT seconded, a resolution for the payment of a dividend at the rate of 6 per cent. per annum, less income tax, on the first preference stock for the six months ended June 30 last.

The resolution was unanimously agreed to; as was also a further motion, proposed by the CHAIRMAN, and seconded by Mr. W. W. CARGILL, for the payment of a similar dividend on the amount called up on the second preference stock.

The CHAIRMAN afterwards proposed the payment of a dividend at the rate of 4 per cent. per annum, free of income tax, on the ordinary stock for the six months ended June 30 last.

Mr. CARGILL seconded the motion, and it was carried unanimously.

The retiring Directors, Messrs. Peter Garnett, John Frederic Harrison, and Samuel Herrick Sands, were then re-elected, as were also the auditors, Messrs. Quilter, Welton and Co.

The CHAIRMAN: The next resolution I have to propose refers to the subject I dealt with when I addressed you a short while ago—that is, the debenture stock. I now move, "That the Directors be authorised to borrow, for the purposes of the Company, such sums of money as they may think proper, but so that the amount borrowed shall not at any time be greater than £150,000, and that all moneys so borrowed may be represented by debentures, debenture stock certificates or otherwise, and may be payable or redeemable in such events and secured in such manner and generally may be issued on such terms as the Directors may think fit."

Mr. GARNETT seconded the resolution, which was carried unanimously.

Mr. CARGILL said he had attended every meeting which the Company had held since its establishment, and at each meeting he had felt greater satisfaction and pleasure at the way the business was conducted. It was very satisfactory to the shareholders of this Company to find that all their telephonic system was conducted in such a way as to give satisfaction to the public and to afford a good profit to the shareholders. He thought that what the Chairman had stated as to the position and prospects of the Company was just as satisfactory as his statements had always been up to the present time. He had no doubt that the shareholders would all join him in passing a vote of thanks to Colonel Jackson

Digitized by Google

and the Directors for the able way in which they had conducted the affairs of the Company. He then moved a resolution to that effect.

Mr. LEAKE seconded the motion, which was unanimously carried.

The CHAIRMAN, in acknowledging the compliment, said that they had had the assistance of the shareholders everywhere where the Company was working, and in many cases that assistance had been very valuable. He was much obliged to them for the compliment they had paid to the Board.

The meeting then separated.

The Edison and Swan United Electric Light Company (Limited).

The annual general meeting of the shareholders in this Company was held on the 9th inst. at the City Terminus Hotel, Cannon-street, under the presidency of Mr. J. S. Forbes.

The SECRETARY (Major Flood Page) read the notice calling the meeting. The report of the Directors was taken as read.

The CHAIRMAN, in the course of his remarks in moving the adoption of the report, said: I think the essence of what I have to say lies in the profit and loss account. That is simple enough. The chief feature about it that has to be dwelt upon is the fact that after charging the current business of the year with everything that can be fairly charged against it, and being somewhat more liberal than in former years upon the item of depreciation, the result shows a profit of £16,221, against £24 in the previous year. It is quite true that in that year, from circumstances which I had to explain at the last meeting, the profit made in the year ended June, 1885, of £12,000 had been reduced almost to *nil* last year, but it is gratifying to see that, as I have just said, £16,221 remains as the profit of the year which has just elapsed, after being liberal in the matter of depreciation and reserve. Now, I believe that that is the whole report, because when I come to deal with the substance of it it assumes the position of the paragraphs in the document itself. First of all the report tells you that the sale of lamps and the business of the Company have progressed in a satisfactory manner, that the profit I have mentioned has resulted, and that during the year the Directors have paid off certain mortgages, and have thus made the financial position so much stronger. Installation work has been more active during the past twelve months. The fact is that the electric light, for internal purposes at all events, is beginning to be appreciated more and more, and year after year the great clubs are beginning to find out that gas, though perhaps somewhat more economical in the mere payment per thousand feet, is not so economical or advantageous as the electric light, and they are rapidly transforming their system of lighting from gas to electricity. The Athenæum Club is so lighted, and we have also lighted the National Club. The banks are also finding out the same thing. They have to pay a large sum for lighting up, and they have large staffs in their employ who have to work in a vitiated atmosphere, and somehow or other humanity does hold its own against avarice in these days, and people who are employing large numbers of other people are beginning to have some regard for the health of those people; in fact, they find it pays, and the banks find that it will pay to use the electric light rather than gas. The electric light is in use at *The Times* office, and I think that gas has been almost entirely superseded by the electric light in the composing room. The light is much better to work by, and that is a fact which is being more and more discovered. It seems to me that that fact is taking root, and as we are in possession of the key of the fortress I trust in time that the large amount of capital, the not inconsiderable amount of anxiety and labour that has been thrown into this Company up to this time on the part of the Directors and of their technical advisers and officers, as well as the patience and forbearance exhibited in so large a degree by the shareholders, will meet with their fitting reward. I think we may take the balance this year as an earnest that that reward is within reach. We have not only advanced substantially in what is called material prosperity, but we have disposed of some of those doubtful points the issue of which at this time last year had not been determined. You know that we are possessors of patents, and I suppose that a large measure of our prosperity will depend on the validity of those patents. This is the second concern in which I have been engaged in which the investments have turned largely on the possession of patents—the telephone and this business of electric lighting—and I have arrived at one conclusion, that any one who stakes his money on a patent is a fool. That is a general proposition which I shall be prepared successfully to defend, if it needed defence, with the experience that we have got before us—I mean until the validity of the patent has been established. We are fortunate in our concern in one respect, that the cost of our patents for a large portion has taken the form of a contingent payment to Mr. Edison. The other portion took the form of an actual payment to another illustrious inventor. If that gentleman and his friends had been in the position Mr. Edison is in, and had only claims on the concern for contingent value after the people who had put their money into it had received a reasonable interest, the position of this Company would have been very different to what it is, and we should have been paying a large dividend. The fact is that we have been obliged to pay for the validity of those patents. We had no mean opponents. Messrs. Woodhouse and Rawson were the principal ones; but I think that they were backed up by other people as partners themselves, whose interests were much in the direction of their interests—that is to say, people who would be very glad indeed to use the Edison and Swan lamp without paying for it. There are plenty of them about. We have tried this matter, and we have succeeded as regarded the only two patents which were really tested—the Edison patent and the Cheesborough patent. We succeeded in the court of first instance, and in both cases those judgments were confirmed on appeal. Though the time for appealing to the House of Lords is not yet expired I think I am right in saying that, as far as we are at present advised, there is no probability that those particular judgments will be challenged in the House of Lords. We succeeded a day or two back in obtaining a judgment against an offender against whom we commenced an action for infringement, and he commenced one against us. We may assume, I think, that whereas this time twelve months the uncertainty attaching to the validity of these patents was such as to give some serious anxiety to the Directors, who, after all, have to take upon themselves the onus of determining whether these things are to be fought or not, the matter has been greatly altered. We are much more certain about it than we were, and my mind is pretty well at ease as to our patents. They have several years to run, and we must make hay while the sun shines. We must while they last take the full measure of these patents, as I suppose they will not be prolonged. We have a fixed policy in our minds turning upon these patents when the protection goes and as to what our position will then be; that is not a new matter for consideration in the lives of men who have lived my life and who were born long before the Reform Bill. They have had to consider the free trade question and protection in a great many forms. We have made up our minds what we are going to do, and that is as far as possible to retain in our hands the manufacture of our lamps, in order that we may secure to the public two advantages—the greatest measure of efficiency and the greatest measure of economy. It is quite obvious that the man who has to manufacture lamps from day to day, and who is always under the pressure of improvement, is the most likely to produce the most efficient lamp, and that the man who has to manufacture a million can do it cheaper than the man who has to manufacture a quarter of a million. We shall retain the manufacture of the lamp, and as time goes on diminish the price consistently with a reasonable profit on it; and at the end of the time for which the patent lasts, we shall have established such a general position, as the vendors and manufacturers of the lamp, that we shall be known as having the best trade mark and the best lamp. That is our policy, and that exhausts really the substance of the report and the substance of the accounts. I may refer, however, to one or two items in the profit and loss account. You will see that we have obtained by the sale of lamps, fittings, &c., and for work done, £65,736 this year, as against £51,998 in the preceding year. That is a substantial increase, some £14,000, and the great increase comes from the lamps. We have had rather more installations, and rather more private work. There is one item which is somewhat exceptional, royalties from Messrs. Woodhouse and Rawson. That firm were allowed by the Court to go on selling lamps under the obligation of keeping an account and paying a royalty in the event of the decision we obtained against them being confirmed. When we got the decision confirmed by the Court of Appeal they proceeded to pay up, and we have thus got out of them £4,217 in respect to the royalties payable to us during that period of about a year. But I think we have a claim against them in respect of the period anterior to this, and we have also a claim against them for the costs in which they were cast and which they have not paid. I suppose they are solvent. We did not wish to abuse our victory. That is not only ungenerous, but it is bad policy, and we shall not press them so long as we are convinced that they mean ultimately to do what is right and pay up. On the other side of the profit and loss account there is another favourable feature that I desire to draw your attention to, and that is, that whereas the stock, principally of lamps and material, carried over on the 30th June last year into the accounts of the current year amounted to £15,001, the stock carried over this year is only £12,868. Of course we are obliged to have in this business a very large number of lamps in stock. I do not know that I am competent to go into all the details in connection with this matter, but if you wish to have the details there are other gentlemen in this room who can supply them; but I may mention that there are lamps of different capacities—so many candles, so many volts—and that fact means a great many varieties of the Edison and Swan lamp, even though that lamp should be, under some general denomination, the same thing. We have also sudden orders coming in every now and then. A man wakes up to the fact that he wants 1,000 lamps, and determines that he will light his place up within a fortnight or so. He takes it as a matter of course that he can get the lamps all at once, although, as a matter of fact, they are not always there. Still, that is part of the general policy, to encourage the idea that people have only got to go to the shop and get what they want. Now, passing on to the next item, we have wages, purchases, cost of installations, &c., £37,159, against £33,430 last year; but there you see that is against the large excess on the other side—£65,736 of receipts, against £51,900. There is an increase there of £14,000, and of course that amount of property was not sold without additional cost, and "wages, purchases, and cost of installations" means the price of material, labour, and many other things for providing these lamps, and so on. Then we come to the item of salaries, Directors' fees, and all those things which excite so much attention generally, and you will be glad to hear that there has been some progress there. That item stood in the accounts last year at £10,853, whereas now it is £6,917. That is not all saving, because some portion of that diminution turns upon an alteration that has been made. The salaries of the engineer and other gentlemen are now in the installation account. Mr. Crisp reminds me that I might make a point by calling attention to the fact that the Directors this year, as in former years, have waived £1,500 of the fees to which they were entitled under the Articles of Association. I think they were wise to waive them. I do not think the Directors ought to have too much prosperity when the shareholders are not prosperous also, but perhaps some day, when you are getting large dividends, you will remember the fact that we have now in these hard times waived the amounts I have mentioned. If you do not think then that these amounts are morally due to us we shall not claim them. The item of depreciation of plant, &c., I next wish to call attention to. Last year there was £1,708, and this year it is £3,281. We found that the machinery was getting

Digitized by Google

older, and we thought it wise to recognise that fact by increasing the amount of depreciation chargeable on that account, and accordingly £3,281 has been written off out of the profits to meet this wearing out. Then we have the Holborn Viaduct rent, &c., and the loss on removal from Benwell, £3,000. That is another thing that we met in the same way. It means early loss and early mistakes being written down now. That is part of our original sin being wiped out. These were losses incurred by bad bargains in former times, and as I have said before we have had to bottom it all and get rid of these bad things as far as possible. We have got rid of them to a certain extent, and we are writing down the loss out of profits. Interest on mortgages last year amounted to £833. We had some properties mortgaged which we have now paid off, except the mortgage on Ponder's End, which we shall pay off as soon as we can. Now, coming to the balance-sheet, that will show you that the capital remains intact. This time last year the capital amounted to £471,298, and it represents that amount now. The gallant secretary reminds me that in that amount are included the 23,564 "B" shares of £5 each, fully paid, amounting to £117,820. That represents Mr. Edison's contingent interest, and you will see that we say the "B" shares are entitled to a fourth of the profits after a cumulative preferential dividend of 7 per cent. per annum has been paid on the "A" shares, and the preferential cumulative dividend is £96,630, which is payable out of future profits. Before Mr. Edison, or the holders of those "B" shares, can touch any money you must have had your 7 per cent., and you must also have been paid this amount which has accumulated of £96,000. I have a great admiration for Mr. Edison, and I heartily wish he may very soon touch a quarter of our profits after we have paid 7 per cent and this amount of arrears. Now the next item is the sundry credit balances, and that stands at £5,799, compared with £13,350 last year, and that reduction made in amounts owing by us is very gratifying. On the other side of that account there is the reverse of the picture. The cost of patents, goodwill, preliminary outlay, loss on working, &c., as per last balance-sheet, was £305,000. That went through the process of diminution by writing off and selling plant, which realised excess in value over and above the valuation put upon it. It now stands at £298,000. That is on the first line, and underneath it is said, "further expenditure thereon £4,467," making together £302,821, less the amount realised by sale of plant, &c., leaving £300,814, plus Mr. Edison's shares £117,000. That makes up together £418,000, and that is capital not covered by really tangible assets. It is the amount you paid to found the business, for patents, for goodwill, &c. When you come to the items underneath you see that we have freehold property (less mortgages) £13,691; then installations in progress, £2,794. That means money coming into our coffers when we have finished the work. Plant and stock is an item standing at £30,045; that is the fair valuation of our stock and plant to carry on the business with. The office furniture is £1,057—there is an increase there during the year of £100. Then you see the item of debtors amounts to £12,946, as against £14,887 last year. Well, that shows that we have got our money in more closely, and these are all good debts and assets. We have cash at the bank and in hand £14,000. All those sums totalled up represent the really tangible assets, which, if sold to-morrow, would realise sovereigns and perhaps more. I think I have been a little exhaustive, but I have now said all I intended to say subject to being called upon to answer questions. I am just reminded that I ought to refer to one other matter, from which you will see how strange it is that other people's misfortunes sometimes help the interests of other people. I am reminded that the fire at Whiteley's was made much worse by reason of the gas. It is quite obvious that where a big fire does set in, particularly in such enormous premises, it is fed by gas pipes which are full of gas all over the place. That is a danger that does not attach to the electric light, at least to the same degree; and I daresay that that will be a consideration with people in time. There is a great agitation now going on about the safety of theatres, and we all know what a dreadful tragedy there was at the Paris Opera Comique. I suppose we shall see in course of time our theatres lighted by electricity. I now beg to propose the adoption of the report and accounts.

Mr. F. R. LEYLAND seconded the motion.

Mr. PRYOR wanted to know what had become of the legal expenses, which must be very large. He would also like to know why the £16,221 of profit was to be applied to the extinction of the amount standing to the debit of profit and loss, because on the face of it there seemed to be £24 to the credit of that account.

Mr. NEIL asked how long the patents had to run.

A SHAREHOLDER asked whether Swan's light was used at Whiteley's.

The SECRETARY replied that a great deal of the electric light was used there, but gas was used in the part of the premises where the fire occurred.

Mr. REW wished to know whether an action had been brought against the Company by the Anglo-American Brush Corporation.

The CHAIRMAN, in reply, said it would be observed in the balance-sheet that they spoke of cost of patents, &c., &c., and further expenditure thereon £4,467, which included the legal expenses incurred by the Company in upholding their patents, and they had from time to time dealt with that matter in a similar way, debiting capital with the legal expenses. They were capital charges. What was the cost of the patents? Some people who did not think it out would consider that it would be the amount paid to the patentee. But then if when the patentee was paid the patent was assailed, and they had to fight in order to establish its validity, the expenses so incurred had to be added to the cost of the patent. That was the view which the Directors took of the matter, and the view of the auditors—that the cost of protecting the patent was part of the cost of the patent itself. Thus it was made a capital charge. They did not know what was going to arise hereafter, and some day there might be amalgamations, and so on, and obviously to charge revenue a very heavy expense incurred solely for building up the patents would be taking money out of their pockets to-day to put it into somebody else's pocket in the future. He had known companies which were very prosperous that paid capital charges out of revenue, but that was because they did not want to excite avaricious competitors into too ready action by paying too large dividends. Poor companies could not do that. In the previous year they debited in the same way £8,104 to capital, the bulk of which also represented legal expenses a year ago. He thought they had every reason to be satisfied with the economical nature of the legal expenses considering the "lights" whom they had to employ. With regard to the question of the application of profit he had purposely proposed the report and accounts, because they had to adopt the report and accounts to confirm the fact that there was a profit. They thought they were bound by justice, and prudence also, to apply that profit to writing down the losses of previous years, rather than distribute it by way of dividends. When they took the business over it was a putting together of two concerns which had not been over wisely administered, though he would not say they were unwisely conceived. There were very great faults and bad bargains made, and now they had to write down the losses which were made in those early days. They had had in the working of the concern great losses. Three years ago they lost £28,000 on the working account. The following year, as the result of a rearrangement, that £28,000 loss was turned into a profit of £12,000, which they wrote down; the profit of £24 made last year was an amount dealing with which did not give them much trouble But now they had a substantial sum, and the question was should they pay it out. They thought it was no good starting a legal hare, and that, therefore, they had better use the amount in writing down the debit to profit and loss, instead of paying it away in dividends. That was a proceeding which came to this, that instead of taking it now they applied the money to the improvement of the property. The key of the patents had to run for six years from November next. That might be considered not a long time, but with the reputation which they had built up, and which they were building up, a good deal might be done in that time. The Edison and Swan interests were happily united in England, but they were equally unhappily disunited on the Continent, and they were cutting each other's throats in France, Belgium, Germany, and other places. They had done a great deal to induce the Edison people abroad to fall into the same happy amalgamation which they had succeeded in establishing in this country, but unfortunately so many were interested in the Edison patents abroad that it was almost impossible to say to whom the patents really belonged. With regard to the question about the Anglo-American Brush Company, they stated in their report:—"Other actions are pending in connection with the Company's patents, but in these the Directors are advised that there is no probability of the judgments of the Courts of Appeal being reversed." That meant that there were actions pending with other people. It was true that the Brush Company had commenced proceedings, having issued a writ. He did not ever undervalue an adversary, but he did not think there was much in the action that was being taken against them by the Brush Company, and Mr. Crisp, who was a very good judge, acquiesced in that opinion. That Company had got what they thought was a patent which this Company was infringing. This Company had got a patent which they knew the Brush Company were infringing, and that was the difference. Upon that ground they were inclined to stand. What the Brush Company in their wisdom would seek to do he did not know, but they on their side had no desire to embitter the controversy. As to the Electric Lighting Act, there was a tremendous kick-up about it last year when he gave his evidence before the Committee. The only concession made to the electric light companies was that they were to have possession for 42 years instead of 21 years. The thing went through Committee, and, on the recommendation of that Committee, into the House of Lords; and then the Board of Trade, who took strong views, tried to bring some clauses into it which had the effect of modifying that concession. The House of Lords would not consent to it, and the measure was withdrawn. This year Lord Thurlow, who was Chairman of the Brush Company, brought in a Bill which went to the House of Lords, and they took the essence out of it—the goodwill. It had gone down to the House of Commons with the goodwill out of it, and as their hands were full for the end of the Session he thought they were not likely to pass it.

The motion was carried unanimously.

The retiring Director (Mr. Shelford Bidwell, F.R.S.) was re-elected, as were also the auditors (Messrs. Quilter, Welton and Co.).

A vote of thanks to the Chairman was then passed unanimously.

The CHAIRMAN, in reply, said it was very gratifying to the Directors to find that after many years of great anxiety they were enabled to present a substantial, and, in their opinion, satisfactory statement of accounts. He thought that their future was an assured and good one, but he hoped they would not reproach him if a few years hence that opinion should be proved to be too sanguine. It was his opinion, and he believed it was shared by his colleagues.

The proceedings then terminated.

CITY NOTES, &c.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July were £23,400; from 1st January to 31st July, they amounted to £150,520; while for the corresponding months of 1886 and 1885, they amounted to £147,560 and £168,040 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 5th, were £2,791, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE SCHOOL OF SUBMARINE TELEGRAPHY
AND
ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, Princes Street, Hanover Square, London, W.

Manager: Wm. LANT CARPENTER, B.A., B.Sc., F.C.S.
Secretary: LEON DRUGMAN, A.S.T.E.
Senior Instructor: H. D. WILKINSON, M.S.T.E.

THIS Establishment is now the largest and the most fully equipped School of its kind. It possesses, among recent additions, several dynamo machines and electric motors, a 6-horse boiler and steam engine, a gas engine, 42 E.P.S. accumulator cells, lathes, &c., as well as several kinds of arc and incandescence lamps and a photometer room. Both theoretical and practical training can therefore be obtained. Since its opening in 1868 more than 3,000 Pupils have passed through the School. At the end of the course of instruction, an Examination for the CERTIFICATE OF THE SCHOOL is conducted by an Examiner of high standing, unconnected with the School. New courses usually commence early in January, May, and September.

For full prospectus, terms, &c., apply to the Secretary, 12, Princes Street, Hanover Square, W.

NOTES.

TRAIN LIGHTING.—The Great Northern Railway are providing electric light in some of their carriages, we believe, by means of accumulators.

CLUB LIGHTING.—The committee of the Carlton Club have decided upon lighting throughout with electric light. The work has been entrusted to Messrs. Thompson and Ritchie.

PROJECTED FRENCH CABLES.—A project has been submitted to the Committee of the French Chamber who have charge of the Budget for 1888, providing for the laying of submarine cables between the east coast of Africa and the Islands of Madagascar and Réunion.

THE CHINESE TELEGRAPHS.—It is stated that the Chinese Telegraph Companies and the Chinese Administration have effected an agreement, to which the Russian Administration is also a party, by which communication is to be established with the Siberian land lines, and a tariff established which is not to compete with the cable companies.

SURGICAL ELECTRICITY.—We understand that the so-called "galvano-cautery" batteries used in connection with the recent operations on the throat of H.I.H. the Crown Prince of Germany by Dr. Morell Mackenzie, were designed by Mr. Thistleton, of Old Quebec-street, W., and contained several simple but substantial improvements.

PHYSICAL CONSTANTS.—The French Société de Physique has undertaken the publication of a complete list of physical constants, according to the results of the best determinations, and has appointed a committee consisting of the following members to undertake the task:—MM. Joubert, Cailletel, Dufet, Lippmann, Romilly, and Violle. The result should be a work of considerable value.

ROBERT STEVENSON'S LIFE OF FLEEMING JENKIN.—We understand that the forthcoming memoir of the late Prof. Fleeming Jenkin will be supplemented by two volumes of Mr. Jenkin's essays and reviews, which have been arranged for publication by Mr. Sidney Colvin and Prof. Ewing, and will contain, amongst other interesting matter, essays on submarine telegraphy, telpherage, and the application of graphic methods. The work will be published some weeks hence by Messrs. Longman.

TYNEMOUTH.—At the last meeting of the Tynemouth Town Council a motion was brought forward and seconded, to the effect that the Town Clerk be instructed to apply to the Local Government Board for sanction to light the new market by the electric light, and to refer the question of obtaining a license to the Trade and Commerce Committee. Against this an amendment was moved, that the electric light be abandoned. On a division, nine voted for and six against the motion, which was consequently carried.

DUNSTABLE.—AMERICAN COMPETITION.—At a recent meeting of the Dunstable Town Council a communication was read from the American Electric Manufacturing Company, stating that their foreign agent, Mr. C. R. Heep, was at present in America, but on his return would at once call upon the Council, if they would leave the matter open. The company expressed their belief that they would be able to give the corporation every satisfaction. The Mayor remarked that if it only had the effect of reducing the price of gas that would be something.

THE RECORDED DEVELOPMENT OF ELECTRICITY IN THE NICE EARTHQUAKE.—The Biological Society of Paris had before them at a recent meeting the case of the telegraph operator who received a powerful electric shock at the moment of one of the earthquake shocks at Nice, which was mentioned in our columns at the time. It appears that the unfortunate man has suffered from partial paralysis in the hand through which the shock was received from the telegraph line. The doctors appear to entertain no doubt that the occurrence was due to a powerful discharge of electricity.

THE CRISIS IN THE AMERICAN CARBON TRADE.—It appears that the intention of the Mutual Carbon Manufacturing Association will not be affected by the break up of the Cleveland ring, and in a circular issued to the local electric lighting companies it is stated that the association has already secured contracts for the supply of 12,000,000 carbons per annum. Efforts are being made to increase this figure to 20,000,000. From some correspondence in the columns of our contemporary, the *Electrical World* of New York, it appears that several firms are disputing the honour of having been the first to back out of the combination.

MAURITIUS.—One result of the recent difficulty in Mauritius will probably be the connecting of the island with Europe by telegraph. For several years this step has been pressed on the attention of the Colonial Office, and its importance has been acknowledged on all hands. Still nothing was done; but during the last twelve months, owing to the isolation of Mauritius, difficulties have arisen and mistakes have been made which might have been avoided had there been an opportunity for ascertaining the views of the Colonial Office. At present telegrams have to be sent to Natal by steamer and are then despatched from Durban, a delay of a month being frequently the consequence.

THE USE OF PERMANGANIC ACID IN SECONDARY BATTERIES.—According to M. Meserole a trace of sulphate of manganese, added to the dilute sulphuric acid in secondary batteries, appears to assist the forming process considerably, especially in batteries of the Planté type. The quantity of manganese should not exceed one thousandth part of the electrolyte, otherwise a precipitate is formed. The presence of manganese in small quantity appears to cause the formation of permanganic acid while the cell is being charged. When the cell is fully charged the characteristic red colour of the acid solution is very apparent, and it is probable that the advantage of its presence results from the oxidation of any sulphate of lead which may be formed on the plates.

TUNSTALL.—A local paper says:—"For four nights last week the inhabitants of Tunstall had an opportunity of seeing the application of the electric light to the purposes of street lighting, Bank-street being lit up with incandescent lamps. A lamp of 17 candle-power was placed in each of the ordinary lamp-posts, and a group of three on the lamp-post abutting on the main street. The light from these three was more powerful than the treble burners with which the street is ordinarily lighted. Parsonage-street, which is about 300 yards long, had perhaps more light than is required for a bye street, and this was supplied by two arc lamps. The whole work was executed by Mr. W. O. Rooper, of Stafford. The light was inspected during the week by the members of the local board."

ELECTRIC GOVERNORS.—M. E. Menges has brought out a device for obtaining the automatic regulation of shunt or series-wound dynamos by means of a solenoid placed either in series or shunt upon the main circuit, and which acts directly upon the throttle valves of the gas or steam engine. It is difficult to discover from the description before us any specially novel

Digitized by Google

feature in this arrangement; in fact, the idea appears to have been put into operation in a somewhat crude form. Our French contemporaries, who are apparently under the impression that this is the only electrical governor in existence, have evidently never heard of Richardson's or of Willans'. M. Menges' invention has therefore produced a thrill of admiration which must be highly gratifying to the distinguished inventor.

THE TELEPHONE IN AUSTRALIA.—The Government in New South Wales has for some time past utilised the telephone as a means of communication between outlying districts, where telegraphic business is not sufficient to engage the whole attention of an operator. The innovation has worked so well that at the present time there are no less than forty telephone stations in New South Wales. In only two instances, however, has the postal department of Victoria employed the telephone in this manner, and even in these cases, it has only been with the object of permitting communication to be maintained with the lighthouse keepers at Point Lonsdale and Cape Nelson. The example of New South Wales, however, is likely to be followed in the future, as several deputations have been promised telephonic communication with stations which cannot now be reached by telegrams.

THE TELAUTOGRAPH.—According to a Paris telegram the writing telegraph, to which the name of Telautograph has been assigned, has been exhibited in that city. It is a little doubtful whether this information is strictly correct, not because writing telegraphs are anything new (Bain's chemical telegraph and Cowper's ingenious apparatus are well known to electricians), but simply because the term "telautograph" has been appropriated by Elisha Gray for an instrument of this description which, according to the latest information from the States, he is still engaged in perfecting. There is, however, already in operation an American Company which makes use of an instrument essentially similar to Cowper's, and this is probably the apparatus exhibited in Paris. In this apparatus the resistance is varied by means of the compression of carbon plates, instead of resistance coils as in Cowper's telegraph.

MAGNUS VOLK'S RAILWAY.—In the House of Commons on Tuesday last Mr. Picton asked the Chancellor of the Exchequer whether he would be good enough to state on what statute or on what authority the exemption from passenger duty of railways on public roads, as in the case of Volk's Brighton Electric Railway, is dependent.—The Chancellor of the Exchequer said that that was not exactly a case of exemption. Volk's Brighton Electric Railway did not fall within the legal definition of a railway, and was not subject to passenger duty. It, however, paid duty in another form, for by a clause in the Customs and Inland Revenue Act of 1883 any vehicle drawn or propelled on a road or tramway by steam or electricity was subject to carriage duty. In reply to a further question the right hon. gentleman said that the words he had quoted confirmed the view that tramways were not liable as railways to passenger duty.

ANNUAL OUTING.—The annual outing of the electrical and engineering staff of the Royal Courts of Justice took place on Monday, the 15th inst., when they proceeded to Egham. Amongst the guests were Mr. A. Grundy, of Baily and Grundy (late electrician at the Courts), Mr. Martin Madders, engineer of the Orange-street Waterworks, Mr. Shurman, engineer to the Law Land Company, and others. On arrival at Egham, a scratch match of cricket was arranged, the result being that Mr. Bamford's eleven beat Mr. Miller's eleven by seven wickets. At the dinner, which was served at the Barley Mow, Mr. Grundy, in the unavoidable absence of Mr. Palfreeman, the chief engineer, took the chair. The toasts of "The Queen," "The Law Courts Staff," "The Chief Engineer," "The Ladies," "The Stewards," "The Visitors," were enthusiastically drunk, after which the party adjourned to the river, where several interesting rowing matches were decided. The party returned to town by a late train, a most enjoyable day having been spent by all.

TELEGRAPH RATES.—In the House of Commons on Friday last Mr. Sinclair asked the Postmaster-General if, considering the facilities afforded to the press for the transmission of long telegrams, he was prepared to make any concession to individuals and private firms desirous of sending telegrams of considerably more than the average length; and if he could see his way, with a view alike to promote the interests of the public and the financial prosperity of the Post Office, to reduce the charge for such telegraphic messages as exceeded twenty-four words to one shilling for the first twenty-four words (the present charge for a message of this length), and a further charge of one penny for each additional four words after the first twenty-four?—Mr. Raikes said that after the fullest consideration he had concluded that it would be undesirable to make any alteration in the tariff of telegraphic messages, so short a period having elapsed since the recent reductions. The experiment could not be made, at any rate, until the financial results of the recent reductions in the price of messages were fully ascertained.

THE OERLIKON DYNAMO.—Mr. B. H. Thwaite writes us from Liverpool as follows:—"That there is no danger of overheating in the working of the Oerlikon dynamo is absolutely proved by those at work in the electro-metallurgical establishment near Turin. In these works there are five Oerlikon dynamos, each working with their full charge (50,000 watts) day and night, with only an intermission of five minutes in the twenty-four hours, without heating. This is the only dynamo tried for the electro-metallurgical (copper) process that would do this, although the best dynamo (I believe from Berlin) had been used." In the article on the Oerlikon dynamo in our last issue we credited the machine with having performed a run of fourteen hours with a rise of temperature of 60°C. in the armature and 35°C. in the field. Mr. Thwaite now writes to substantiate a much more remarkable performance, and we can well believe that, as he says, no other machine from Berlin succeeded in developing 50,000 watts for twenty-four hours "without heating" (words which he underscores twice). It seems to us, however, that our own account is better calculated to inspire confidence in the merit of the design than any such phenomenal result as described above.

THE THUNDERSTORMS.—On Tuesday and Wednesday last severe thunderstorms took place in all parts of the country, and several fatal accidents are reported. In London a man who had taken refuge under a tree in Maida Vale was killed, another man was killed on Carlton Bridge, Harrow-road, and a third who had sought shelter under a tree in Portsdown-road was also killed. Several people in this neighbourhood are also reported to have been knocked down and rendered insensible. In Birmingham district three men were killed, and considerable damage was done to property. In London several trees and buildings in Highbury and Canonbury were struck, and we also hear of a similar case in Cannon-street, though it appears that not much damage was done. About half-past eight a remarkable flash was witnessed in the neighbourhoods of Lambeth and Westminster, where a narrow

Digitized by Google

line of forked lightning is described as having suddenly broken up into thousands of balls, like the discharge of a skyrocket. Although accompanied by torrents of rain, the storm was remarkable for the absence of wind and the consequent slowness with which it travelled. In the west of London the storm began at five o'clock, and lasted nearly four hours, passing away towards the south-west. A print from a negative taken during Wednesday night's storm by an amateur who occupied a good position for view at Earl's-court, is described as showing a flash of forked lightning in the act of *rising* from the ground, with a somewhat faint flash of a return spark travelling downwards.

BRADFORD, YORKS.—At a recent meeting of the Gas Committee of the Town Council, Mr. Lobley asked what steps had been taken by the committee with regard to the furtherance of electric lighting. He put the question because he was a member of the Markets and Fairs Committee, and they had had several applications in reference to supplying electric light to the market property.—Mr. Alderman Priestman said that the committee had collected much information respecting the electric light, and he had hoped before now to have come to the council with a proposition for spending a sum of money to place down an extensive installation before the coming winter. Owing, however, to the immense amount of work which had been placed upon the town clerk and his office in consequence of the Jubilee celebrations they had not been able to get along with the work so fast as they would have liked to do. The work was again proceeding; but, seeing that summer had so far advanced, it was quite impossible to complete it before winter. On the whole it did not seem worth while to spend the money just now, because the interest upon the amount of money expended in the meantime would be lost. In all probability there would be improvements in electric lighting, and this would enable them to get a more perfect system by waiting than they could at present obtain.

TENDERS FOR STREET FIRE ALARMS AND TELEPHONE COMMUNICATION AT HORNSEY.—The Hornsey Local Board have received the following tenders for street fire alarms and electric communication throughout their district, the amounts being for Section A, Section B, and for maintenance per annum, respectively:—Radcliffe, Birmingham, £927, £458, £100; Jennings, Lambeth, £760, £609, £35; Stuart, Twickenham, £829, £492, £75; Siemens, Westminster, £800, £500; Sax, Bloomsbury, £755, £362, £80; Telegraph Manufacturing Company, £725, £362, £100 to £120; Blackburn, Nottingham, £660, £340; Reid Bros., Wharf-road, N., £702, £290; Sharples, Preston, £649, £340, £90; Nelson, Leeds, £616, £356, £60; Theiler, Canonbury, £640, £300, £120; Eidsforth and Mudford, Holloway, £577, £320, £42; India Rubber Company, Silvertown, £550, £260, £86; Fowler, Lancaster and Co., Birmingham, £389, £205; Robertson and Sunderland, Halifax, £393, £170; Blenheim, Egham, £276, £144, £10 (accepted). The Exchange Telegraph Company tendered only for Section B, £376, and maintenance £36. Durham, Stockport, for fixing telephone only, £500. It will be seen that for the A district the highest and lowest tenders were £927 and £276 respectively, for the B district £609 and £144, and for maintenance £120 and £10 respectively.

THE ELECTRIC MOTORS OF THE THOMSON-HOUSTON COMPANY.—The Thomson-Houston Company have for some time past been giving their attention to the construction of electric motors as well as to the development of an electric railway system. It does not appear that they have succeeded in adapting their remarkable method of dynamo construction to the requirements of electric traction, and for this purpose they have now brought out a much more commonplace looking machine. The new motor consists of a pair of upright cylindrical field-magnets, with substantial pole-pieces at the top, and a drum armature with a special winding, the yoke-piece being merged in the bed plate. The machines are shunt-wound, and upon constant potential circuits they are said to be practically self-regulating under all loads, while the brushes do not require adjustment, and no sparking is observable. A commercial efficiency of over 90 per cent. is claimed. Great care has evidently been taken in the mechanical construction of these machines. The base is heavy and the standards which support the bearings for the armature shaft are very strong and stiff. This is all the more essential owing to the position of the armature above the field, but it necessarily results in a somewhat heavy machine; indeed, although we have not as yet obtained the figures, yet we have no doubt whatever that as regards weight per horse-power the construction cannot in this respect compare favourably with motors of English design.

AN ELECTRIC FREIGHT RAILROAD.—The ease and slight expense at which an electric railroad can be operated in large works already provided with a dynamo for electric lighting is well shown, says the *Electrical World*, in the venture recently carried out by the East Boston Sugar Refinery at East Boston. This refinery, which is the largest in New England, is situated about 1,300ft. from the docks where the raw sugar is unloaded from the ships. Formerly the hogsheads and bags were loaded on a railroad truck drawn by horses, the work being such as to tax the animals very severely and necessitating frequent changes. As the refinery is provided with a 150-light Edison plant, it was determined to put in an electric railroad, and the installation was undertaken by the Sprague Electric Railway Motor Company of New York. The rolling stock consists of two flat cars, one of which carries the motor of fifteen horse-power at its forward end, together with a raised platform, upon which are placed the regulating and reversing switches. The cars are capable of taking a load of 12 hogsheads, equivalent to 30,000lb. The current is taken from the lighting dynamo and led to the motor from an overhead wire and trolley, the track being used on return. With the electric railroad the work of transferring can be done in one-fourth the time formerly required with horses; and although ships are constantly unloading at the docks the limiting capacity of the railroad to handle the work has not yet been reached. The motor operates without noise, and although the track is always in bad condition, being invariably covered with sugar and molasses, no difficulty in operation has yet been experienced. Another interesting feature is the fact that thus far no appreciable increase in coal consumption due to the operation of the electric railroad in connection with the lights has been noticed.

SUGGESTED EXPLANATION OF THE VARIATIONS IN TERRESTRIAL MAGNETISM.—In another note we give a brief account of the important researches on the discharge of electricity through gases which has recently been communicated to the Royal Society by Prof. Schuster. The paper contains also a remarkable application of the results to the explanation of the cause of the diurnal variations in terrestrial magnetism. Prof. Balfour Stuart had already suggested that in the upper regions of the atmosphere the air currents may, owing to the lines of force of terrestrial magnetism, have electric currents circulating in them. This suggestion has received some support from mathematical considerations, which seem to indicate that the cause of the variations is to be found in the upper regions of the atmosphere;

Digitized by Google

but the difficulty has been to account for the starting of such currents, which would require an E.M.F. far exceeding anything which can be assumed to exist ("which could possibly exist," says Prof. Schuster) in the atmosphere at these heights. "But," he continues, "as there are very likely continuous electric disturbances going on, such as we observe in auroræ and thunderstorms, the regions within which these discharges take place would act as conductors for any additional electromotive force, however small, so that any regular motion, such as tidal motions, could very well produce periodic effects affecting our magnetic needles. If these original discharges increase in importance, then, according to the results obtained in this paper, the currents due to the smaller periodic causes would increase also, and they may increase in a very rapid ratio. We know that the electric discharges in the upper regions of the atmosphere are considerably stronger at times of many sunspots, and this may account for the fact that at those times the amplitude of the daily oscillation of the magnetic needle is considerably increased."

Long Distance Telephony.—In the House of Commons on Tuesday last Mr. Jacob Bright asked the Postmaster-General if he was aware that there was communication by telephone between Hamburg and Berlin, between Rouen and Paris, and between towns widely distant from each other in the United States; whether his department had from time to time received representations from Manchester in favour of telephonic communication between Manchester and London; and whether he would take steps that what was done in other countries might also be done in England, to the advantage of the commerce of the country.—Mr. Raikes: I have been informed that telephonic communication has been established between Hamburg and Berlin, Paris and Rouen, and between other towns on the Continent of Europe, and also in America. The Post Office has not received representations from Manchester in favour of telephonic communication between that town and London. The United Telephone Company recently asked the terms upon which the department would provide telephone wires between London and Manchester, but up to the present time I have received no answer to the letter which I have caused to be addressed to them on the subject. Having regard to the cheap and swift means of communication which at present exist by means of the telegraph between the principal towns in the United Kingdom, I am inclined to think that it is extremely doubtful whether there would be much public advantage in establishing telephonic communication generally between those towns.—Mr. Jacob Bright: Would the right hon. gentlemen say whether it is practicable to have telephonic communication between Manchester and London, and whether there would be any difficulty in establishing such communication?—Mr. Raikes: I am advised that it is practicable to do so, but there would be considerable expense in procuring new way-leaves, as the poles at present in use could not be made available for telephonic purposes. The machinery would be expensive, but, subject to that, I believe there is no practical impossibility.

"Experiments on the Discharge of Electricity through Gases."—In the number of the *Proceedings* of the Royal Society which has just appeared there will be found a paper by Prof. Schuster, F.R.S., containing an important contribution to our knowledge of the phenomena of the discharge of electricity through gases. The principal result established by these researches is the following:—"A steady current of electricity can be obtained in air from electrodes at the ordinary temperature which are at a difference of potential of one-quarter of a volt only (and probably less); provided that an independent current is maintained in the same closed vessel." In other words, while a continuous discharge is passing through a vacuum tube the gas acquires the property of conducting crossways under an E.M.F., which, says the author, "I believe to be indefinitely small, but which the sensitiveness of the galvanometer I was using has prevented me from tracing with certainty below a quarter of a volt." He then shows that this leads to the important conclusion that "there cannot be a finite difference of potential between a gas and a metal in contact greater than that amount." This conclusion has generally been tacitly assumed in discussions of contact potential, and it is therefore the more satisfactory to obtain an experimental proof of its correctness. Prof. Schuster accounts for the observed facts upon the following theory:—"If the two atoms of a gas making up the molecule are charged by opposite electricities, but are held together in addition by molecular forces, a finite force is required to overcome the latter. But as soon as that force is overcome and the atoms themselves are set free to diffuse and constitute a current, these atoms will be able to follow any electromotive force which we may apply. If, then, we have auxiliary electrodes, these electrodes will establish their electric field, which we can never screen off completely from any other part of the vessel except by closed surfaces. The atoms, with their positive and negative charges, will diffuse across to the auxiliary electrodes and give off their electricity to them. No finite difference of potential is required in the auxiliary electrodes, because even if there is work done in making an atom interchange its positive for negative electricity, that work is undone again at the other pole, where atoms of a similar kind interchange negative for positive electricity."

The Technical Education Bill.—Prof. Silvanus Thompson, in *The Times* of Monday last, expresses the profound distrust with which technological teachers regard that provision of the Bill now before Parliament which practically puts all the control of technical education in the hands of South Kensington. In the course of his letter Prof. Thompson says:—"I happen, Sir, to know something of the working of the Science and Art Department, having at one time come into relation with it as a student, at another time as a teacher, and in each case have been driven by its redtapism to dispense with the aids which its organisations offered. My own fees at the Normal School of Science I paid rather than enter as a free student under the impracticable conditions that environed the studentship awarded to me. I have long ceased to teach under the conditions imposed by the department—conditions which tend to sterilise and fossilise all good work. It would be quite impossible to carry on much of the present work of the City and Guilds' Technical College here at Finsbury if the arbitrary rules and regulations of the Science and Art Department were to be imposed upon us. The rules of the Science Directory, for example, would entirely preclude a grant being earned on any one of our students in practical chemistry, because our laboratories, which we believe to be not only more modern but better than those prescribed by the rules of the Science and Art Department, do not accord with the stereotyped prescriptions issued from South Kensington. To put our chemical classes under the rules of the Science and Art Department would simply ruin them. If I turn to the branch of science that is my own pursuit, physics, I find that it is, by the inexorable rules of the Science and Art Department, cut up arbitrarily into two 'subjects'—(1), heat, sound, and light; and (2) electricity and magnetism. If I get together, say, a class of apprentices from the optical workshops of London, and teach

Digitized by Google

them optics, or if I get a class of young engineers and teach them heat, then by the rules of the Science and Art Department this is not technical education at all; there is no grant for such teaching. If I teach the opticians what they do not want, heat and acoustics, as well as their optics, then I am giving them technical instruction. Or I may teach them building construction, or geology, or zoology, or naval architecture (not that I know anything of these branches of science) and I am equally giving them technical instruction, for these are subjects 'prescribed' as such by the Science and Art Department; but directly I settle down to teach these apprentices the optics that they want to know—the one subject that is technical to their industry—I am no longer giving technical instruction as defined by this Bill."

TRAIN TELEGRAPHY.—"Telegraphing to and from a moving train, for which the above seems to be the best short title, is getting (says the American *Railroad Gazette*) to be an old story on the Lehigh Valley Road, the operators of the Consolidated Railway Telegraph Company having travelled on three trains each way daily between Perth Junction and Easton now for some months. Several modifications and improvements have been made in the apparatus and plant (if a thing of which there is so little may be dignified by the word "plant"), and the facility with which the work is now carried on is such as to give added promise of the useful career in store for this invention. It was very soon discovered when the original apparatus was tried that the distance at which a current could be induced was not by any means so limited as had been anticipated, and that ordinary line wires could be successfully used. In practice it is found, however, that a separate line is more satisfactory, for the reason that most of the ordinary lines of poles make occasional detours into swamps, over mountains, &c., and thus interrupt the operators, though the trouble from undesired currents from other wires on the same poles is found to be hardly worth noticing, "quantity" currents having little or no effect upon the "intensity" currents used in the train system. A pole line is preferable to a wire laid along the rails, for the reason that it makes so much less work for the line inspector. A well built pole line on short poles (about as high as a car roof) is cheap and durable, and requires comparatively little attention from an inspector, while tracks must of necessity be constantly tampered with by repairers, and thus keep the wire inspector always on the go. A pole line is especially desirable on a new road, for it can be duplexed and used for ordinary business from office to office, thus in most cases providing for the whole business of the company and the towns on its line by a single wire; and an aerial line, as is well known, has great advantages over one on or under the ground in its freedom from retardation by the earth. The metallic roof of a car and the truss rods on the under side thereof have been connected with each other and successfully used as the induction coil, so that it seems quite likely that the convolutions of wire can be dispensed with. The company now use a telephone receiver at both ends, the vibrator of the sending instrument sending the currents so that the buzzing, which sounds like that of a very shrill bee, is exactly reproduced in dots and dashes in the telephone. To read these dots and dashes is like reading Morse characters made by a steam whistle, which to most operators is not so pleasant as the familiar sounder; but the train operators find no difficulty in it, nor are they disturbed by the noise of the train, even with the windows open. Already the Lehigh Valley has experienced the value of the service in some typical cases, one of which was that of a breakage in the engine, which delayed a train some five miles from a telegraph office, and which under ordinary circumstances would have necessitated a waggon or foot trip that distance, but which by the aid of the apparatus on the train was settled at once, a relief engine being sent for and brought to the aid of the train in about ten minutes."

THE MELTING PLATINUM STANDARD OF LIGHT.—M. Violle, in a statement which he has recently submitted to the Académie des Sciences, deals with the comparative radiations from melting platinum and melting silver. One of the metals was introduced into the little decimal lamp of Dr. Siemens, which consists essentially of a box pierced with a hole one-tenth of a square centimetre in area. Immediately behind this hole is the metal in the form of a thin ribbon traversed by a strong current of electricity, which is raised in intensity until the point of fusion of the metal is reached, when its radiant power can be observed. In this way M. Violle found that the total radiation from melting platinum is 54 times that of melting silver. This ratio of total radiant energies, while very considerably on the side of the platinum, is yet much lower than the ratio when luminous radiations only are compared, in which case it is as much as 1,000 to 1. In the course of his observations, M. Violle admits that Mr. Methven is correct in stating that in all flames there is a region of constant radiant intensity. For his own experiments upon the comparative luminosity of the radiations from molten silver and molten platinum, M. Violle employed, as an intermediary, the Hefner-Alteneck amyl-acetate lamp, and which, according to his determination, is related to the other photometrical standards by the ratio as follows:—1 Siemens = 1·95 Hefner = 0·832 Methven = 0·208 Carcel = 0·1 Violle. Thus the radiation of light from a square centimetre of molten silver is less than 0·02 Hefner-Alteneck. Mr. W. J. Dibdin, in his report on photometry to the Metropolitan Board of Works, to which we referred last week, gives the following description of his method of working with the platinum standard:—"Unfortunately I have been unable to try the precise plan suggested by M. Violle for obtaining a standard from platinum at its melting temperature; but in lieu of this I have tried a device which gives promise of practical results. The method adopted was to heat to its melting point, by means of an oxy-hydrogen flame, a piece of platinum foil placed behind a steatite screen perforated with an aperture smaller than the portion of platinum actually incandescent. This arrangement, while simple in operation, has afforded very promising indications, and seems well worthy of further experimental observation, as there can be little doubt but that an easily worked and reliable system for obtaining a steady light from molten platinum would find ready acceptance as being definite for all time. When working by this method, the oxy-hydrogen flame is gradually increased in intensity until the platinum foil melts. When this happens the oxygen is turned off, and a fresh portion of foil, which is carried on two rollers, one on each side of the aperture, is brought into position, and a second experiment made; and thus successive readings obtained, if necessary, in rapid succession. The foil is wider than the portion actually perforated by the intense heat, so that by turning a winch-handle, a fresh surface is almost instantly obtained. The operations involved in testing are thus about a quarter of a turn of the winch-handle, and turning the oxygen on and off at the beginning and end of each test respectively. The aperture in the steatite screen is about one-fifth of an inch in diameter, and allows light equal to a little more than two candles to pass to the photometer disc. While the proposition to obtain a standard light by this means is theoretically satisfactory, and the preliminary practical results have been very promising, the details are as yet insufficiently worked out to compete against more established systems."

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 289.)

Now that the practical success of telephony had been assured it became the duty of the Crown to consider the position of the companies in respect of the monopoly of telegraphic communication which it had acquired in virtue of the Telegraph Act of 1868; the result being that an action was entered against the Edison Company just previous to the amalgamation, and service was afterwards accepted by the United Company. The case came on in the Exchequer Division, before Mr. Baron Pollock and Mr. Justice Stephen, on 29th Nov., 1880, and occupied the attention of the Court on four successive days, being then adjourned for the preparation of the judge's decision. The facts of the case were not in dispute on either side, and the entire issue rested upon the interpretation to be given to the term "telegraph" in the Act above cited. The Attorney-General, for the Government, argued broadly that a telegraph meant an instrumental means of communicating intelligence, and if systematically undertaken by a third person in consideration of money paid, it would become an infringement of the Act even if the telegraph was not of an electrical nature at all. On the other hand, it was argued for the company that no communication by telephone was a telegram within the meaning of the Act, because the apparatus and methods are essentially different, and affidavits were put in, in which a number of distinguished men of science upheld the absolute novelty of the invention, and the impossibility of confounding the telephone with any existing type of telegraph.

Statements of this character were made by Sir Wm. Thomson, Prof. Stokes, Dr. Fleming, Prof. Tyndall, Lord Rayleigh, and Dr. Hopkinson. Upon the other side affidavits were read from Mr. Barlow (the inventor of the logograph), from Mr. Warren de la Rue, who described the Reis telephone, and from Mr. Preece, Sir C. Bright, Mr. Latimer Clark, and Prof. Hughes. On Monday, December 20th, Mr. Justice Stephen delivered a written judgment, the crowded state of the court evincing the widespread interest which had been excited. The judgment, which had evidently been prepared with the greatest care, and occupied a considerable time in delivery, is remarkable for the extremely able and discriminative manner in which the technical points are dealt with, and in this respect it contrasts most favourably with certain scientific expositions and definitions which have since been delivered from the Bench.

It is a matter of history that judgment was delivered in favour of the Crown. His lordship commenced by a careful and detailed description of the instruments and methods of working of the Edison Company, and after citing the clauses of the Telegraph Act which bore upon the question at issue, proceeded as follows:—"In simpler language, the Postmaster-General is to have the exclusive privilege of transmitting messages or other communications by any wire and apparatus connected therewith used for telegraphic communication, or by any other apparatus for transmitting messages or other communications by means of electric signals. The result of the definition seems to be that any apparatus for transmitting messages by electric signals is a telegraph, whether a wire is used or not, and that any apparatus, of which a wire used for telegraphic communication is an essential part, is a telegraph, whether the communication is made by electricity or not. It would include, on the one hand, electric signals made, if such a thing were possible, from place to place, through the earth or the air; and, on the other, a set of common bells, worked by wires pulled by the hand, if they were so arranged as to constitute a code of signals." It therefore appeared to him that, although there was no reason to doubt the statements of the distinguished men of science who had testified as to the novelty and the scientific merit of the instruments, yet he must hold their evidence to be beside the mark.

The arguments for the defence, which had been based upon the distinction in the method of working the telephone and the telegraph, appeared to him to apply equally to the Wheatstone A B C or the Hughes type writer, in neither of which was any distinctive code of signals employed. Still more did such reasoning apply to the Cowper writing telegraph; if, as had been said, a telephone line was merely an extended speaking tube, then the writing telegraph was nothing but a long pen. But although this instrument had not been invented when the Act was passed, no one would dream of asserting that its provisions did not apply thereto. He held that the telephone was a telegraph within the meaning of the Act. Judgment was accordingly delivered for the Crown.

Subsequent events have not in any way affected the opinion to which we gave expression at the time, that the decision was one which common sense, as well as law and equity, would uphold. The nation had acquired a monopoly of the telegraph system for the public service at a price and under conditions which proved the intention of the Government to acquire and maintain the exclusive control of any species of communication in which telegraphic apparatus were employed for profit. Had the decision been otherwise there was nothing to prevent the railway companies from equipping their lines with telephones, and competing with the Post Office for the transmission of public messages.

The United Telephone Company, upon the other hand, was probably well advised in putting the matter to the test, and although the royalty of 10 per cent. upon the gross receipts of the Exchange service, which, as a consequence of the judgment, is enforced by the Post Office, is undoubtedly a heavy burden upon their resources, yet it is one which they and their subsidiary companies have proved themselves perfectly well able to bear. The Post Office has, moreover, shown itself a generous taskmaster, and in the matter of long distance or inter-urban telephony, has acted with due regard to the public interest.

It should be here explained that in the Telegraph Act of 1868 private telegraph lines are expressly exempted from its operation, and it therefore still remains open to any individual or corporation to erect and maintain a line of telegraph for private use over any distance provided that such line terminates at each end in premises occupied by the same individual or corporation. Railway companies are thus entirely free from the control of the Post Office as regards their telegraph lines, so long as they are employed solely on the business of the company; and, similarly, the telephone companies pay no royalty on private lines erected for the use of a single individual. If, however, such a line be connected between premises in the occupation of two or more distinct persons, the royalty becomes payable in respect of such service. It is in part for this reason that the United Telephone Company has not seen its way to adopt any of the systems which are sometimes employed in America and on the Continent for cheapening the service, in say, suburban districts, by placing several subscribers upon a single line wire.

Before leaving this part of our historical survey we desire to correct any erroneous impression that may have been conveyed in the opening chapter by the passage relating to the British Post Office having rejected the offer of the telephone patent rights in the first instance. Those rights, it would seem, were really never offered to that or any other Government department of this country, the Crown having taken care to let it be known from the outset that they regarded the Telephone service as coming under the Telegraph Acts.

(To be continued.)

INCANDESCENT LAMP MANUFACTURE.—XXII.

BY J. SWINBURNE.

Testing (continued).

The chief consideration in the photometry of incandescent lamps is the standard of light employed.

It is strange that the incandescent lamp itself as a standard of light has not received more attention; it has been proposed, but the subject has never been thoroughly gone into. The first difficulties that arise are those of measuring the carbons. These could no doubt be surmounted by using a thick carbon,

Digitized by Google

such as a graphite pencil lead. Such a carbon can be easily measured with sufficient accuracy. A perceptible proportion of the power is lost in the joints in large current lamps, but this can be eliminated by making two or more lamps with carbons of the same diameter, taking the same currents, but of different lengths; the resistance hot per inch or centimetre of carbon can thus be obtained. Only a part of the carbon need be exposed, so that the part that gives light in the direction required is all at the same temperature. The next difficulty is the alteration of the resistance with age. This can be avoided by defining the temperature as efficiency, and taking the power only into consideration, not the electromotive force or current. The errors due to differences in degree of exhausting are probably too small to be perceptible.

It is unfortunate that the Light Standard Committee of the British Association does not number more lamp makers among its members, as there would seem to be little difficulty in making an incandescent lamp standard of light which would be easy to use and accurate.

For practical purposes the Methven standard is the most convenient. This consists of a 16-candle argand burner with a screen in which is pierced a small rectangular hole, so that only a small portion of the light is thrown on the photometer screen. The hole is cut of such a size and in such a position that the light is equal to that of two candles. Mr. Methven finds that, if the flame of the burner is kept at a certain height, the light given through the hole is equal to two candles, whether the gas is of good or bad quality. Photometers with Methven's screens can be got from Messrs. Wright, Westminster. The photometers supplied must be altered before use, as the standard burner is movable, whereas it should be fixed, as it has to be close up to the screen so that the two candles may balance the light of the lamp tested, and the graduations are not then correct. The screen is the ordinary grease spot with mirrors, so that both sides of the screen may be seen from the front at the same time.

The lamp is mounted on a holder, which can be moved to and fro, so that the position of balance can be found. The first thing to do is to graduate the photometer. Suppose the lamps range up to 20 or 25 candles, the end of the lamp travel may be marked 30 candles. The scale is then graduated in candles from 30 down to one or two, which will come close up to the screen. A slide rule set for finding roots will save the trouble of calculating the positions of the marks.

If such a standard as the pentane or amyl acetate is preferred it is placed on the mark corresponding with the candle-power it is supposed to give, and the Methven standard is moved up to balance it. When the position is found, it is marked ·3 candle-power-watt, as the efficiency the lamps are to be tested at is controlled by the position of the Methven screen. If the photometer is in London, where the gas is fairly uniform in quality, and if the Referee's standard is preferred, the Methven screen may be taken off, so that the 16-candle burner is exposed, and this burner is then put with its centre the same distance from the grease spot as the 16 mark on the lamp scale. Any gas burner is then placed on the lamp scale, and moved till it balances the 16-candle burner; the screen is then replaced, and the Methven standard moved up to balance the second burner. The point at which it balances is marked ·3 again. The fault in a Methven standard is its inaccuracy when close to the grease spot. If instead of a flame a solid body were the source of light, the illumination of the grease spot would vary inversely as the square of the distance from the screen; that is, provided the screen is not so close to the grease spot that the solid angle subtended by the hole is different at different points on the grease spot. The flame does not emit light like a solid at uniform temperature all over, so that near the sides of the hole where the line from the grease spot would cut the flame obliquely—so that a greater length of it would be in the flame—there is more light sent to the grease spot. This inaccuracy is small, and does not make much difference in practical work, but it is best to fix the standard and move the lamp. If the Methven standard is moved, the pointer must be put so that the distance is measured from the plane of the screen, not from the centre of the burner or the point between the two, as it is sometimes. The Methven screen has the screen itself made of silver. It is difficult to see the reason for this extravagance, as a silver hole does not let any more light through than a hole of any other metal.

If it can be managed, the lamp should be run from secondary cells. The electromotive force can be adjusted as in the case of flashing. A final adjustment can be made by any form of rheostat which will absorb two volts or so. Of course a dynamo can be used, resistances being arranged to control the electromotive force.

A voltmeter and ammeter are also necessary.

The testing is done by girls, and there is sometimes some difficulty in getting any who understand decimals. The testers must find the volts and amperes needed to give ·3 candle per watt. If a lamp is run at random, and is found to give, say 13 candles, and to take 50 volts and 1·2 ampere, the efficiency might be got by dividing 13 by the product of 50 and 1·2, and thus finding if the lamp is too bright or too dull, and trying again, and so on. Such a process would be quite useless in commercial work; so it is necessary to arrange the apparatus so as to overcome the difficulty more or less. The best way is to use a wattmeter. The wattmeter is not graduated in watts, but in the candles a lamp should take at ·3 candle per watt. The tester then turns the lamp up to, say, 15 candles, and looks at the wattmeter; if it reads more than 15 candles it is too dull, and if less too bright, and she turns it up or down and takes a new reading. When the candles on the photometer agree with the wattmeter, the volts and amperes are read off on the voltmeter and ammeter, and the lamp labelled.

In large works the lamps need only be put into boxes or trays according to the volts, being classified as 16, 18, or 20 candle lamps. But if many lamps are used for arc light circuits it is best to label each lamp with the volts and amperes at ·3 candle per watt; the resistance or candle-power can then be obtained if wanted. If the lamps are all made accurately of the same surface they will of course come out at the same candle-power, and testing will be a very easy matter; but in practice they do not come out quite so well, and it is necessary to arrange the testing so as to work with lamps of all sizes.

The chief difficulty is to get an accurate wattmeter; a Siemens dynamometer will not do, as it is not direct reading. The wattmeter must also have its current coil of no appreciable resistance, and the pressure coil in shunt to the lamp and current coil, or else it must be compensated according to the writer's method. The same remarks apply to the voltmeter and ammeter used. If the ammeter is of very low resistance, so that the resistance of the ammeter and the leads are inappreciable in comparison with the lowest resistance lamp made, the voltmeter must be in shunt to both the lamps and ammeter, otherwise the current through the voltmeter will go through the ammeter too, and will cause serious error. The current through a voltmeter even of 8,000 ohms will cause a serious error if it passes through the ammeter when a 110-volt lamp is measured, especially if it is a 10-candle lamp. Similarly the loss of volts over the leads and ammeter may cause an error in a low-resistance lamp, such as for 10 amperes and 6 volts. The error is lowest when the voltmeter is in shunt to the ammeter, as the power absorbed by an ammeter is less than that taken by a voltmeter. This error can be compensated by arranging a few turns of the main circuit round the voltmeter backwards, so that they subtract an effect equal to that produced by the fall of potential over the leads and ammeter.

If a sliding voltmeter or sliding ammeter, such as the well-known graded galvanometers of Sir William Thomson, are used, they can be made to perform the calculation instead of the wattmeter, though not quite so quickly. The ammeter and voltmeter must first be carefully calibrated, and it will be found better to put in new scales, as the scales supplied read from 1 to 45, and the voltmeter is wanted to read to 120 or so, and the ammeter from ·4 to 1·5 for ordinary work. If the scales originally in the instruments are found correct at the position of the magnet box necessary for convenient

Digitized by Google

readings, two new scales may be gummed to the glass inside them, and may then be marked to read directly in volts and amperes. The ammeter will now have three scales, the original from 0 to 45, one from 0 to 2·25, which is used for the current in the case of low-tension lamps, and one from 0 to 1·125 for high electromotive force. These scales are, of course, easily graduated from the original; but, if preferred, one new scale only may be used, reading from 0 to 1·5 amperes. The front of the magnet box is sometimes provided with a projection to facilitate reading its position on the scale on the wooden base, but if this is not provided, a piece of thin sheet brass may be soldered to the bottom of the box so as to project. On one side of the groove in the base borad marks are found by careful calibration, at which the scales read directly in amperes. On the other side a special scale is made, and is so marked that if a lamp takes, say, 60 volts, the ammeter, when the front is put at the 60 mark, will read the number of candles on the ordinary scale that a lamp with 60 volts and the current through the ammeter would give at ·3 candle per watt. Thus the mark for 66·6 volts is at the position in which there would be a reading of 20 with one ampere, and so on. This scale is very easily made by keeping a constant current through the ammeter and finding the position of the marks as the readings of the ammeter vary the numbers on the scale.

When a lamp of unknown candle-power is tested, it is run at, say, 17 candles. Suppose it takes 102 volts, the magnet-box is put at the mark 102 volts, and the reading on the original scale observed. If this is 17 candles, the lamp is running at the right efficiency; if the reading is less than 17 candles it is running too bright, and so on.

New readings are then taken with the lamp a little brighter, or duller, as the case may be, till the candle-power on the ammeter corresponds with that on the photometer. The magnet-box is then moved to the mark for reading the current, and the volts and amperes are read off and marked on the temporary label fixed to the lamp. If all the lamps are tested at the same efficiency it is only necessary to mark the volts and amperes, as the candle-power can be calculated from them. It is generally best, however, to have all three marked, as that affords some check on the testers, as if the watts multiplied by ·3 do not give the candle-power the lamp has been inaccurately tested. This is only a partial check, as it does not show that the reading on the ammeter really agreed with the candle-power of the lamp; but the girls who do the testing do not understand these points, and think that every lamp can be checked by mere inspection, and are therefore careful. The current should be taken to two places of decimals.

If a lamp has a flat carbon the ratio of the flat surface to the projection of the cylinder of the same total surface as the flat carbon is found by measuring the carbon with a michrometer.

The difference is allowed for by moving the standard lamp further from the screen. The standard lamp or gas burner is made to slide over a graduated scale, so that it can be put in the right position at once. If a lamp is to be tested at any other efficiency than ·3 candle-power-watt, the burner is moved to the mark corresponding to the efficiency required, and the testing is done in the usual way. The lamp is then labelled, say "80 volts, 1 ampere at ·25 c.p.w." If the candle-power is also to be marked on, the standard burner must be moved to ·3 candle per watt to take the reading, otherwise the candle-power reading would be wrong.

If the voltmeter and ammeter are of such a form that the sliding arrangement is not applicable, the photometer may have a scale attached which will perform the necessary calculations. The moving lamp holder has an index which not only reads the candles, but stretches over a scale which runs the whole length of the photometer slide. This is made of sectional paper, as usually used for curves. Lines are drawn parallel to the direction of the movement of the lamp. These lines correspond to the electromotive force from, say, 20 to 120 volts, so that if curve paper marked in 20ths of an inch are used, the whole scale is 5in. broad. Curves of currents are then drawn in such a way that when the lamp is giving any candle-power, such, for instance, as 20, the intersections of the electromotive force lines and the current curves under the index give the watts, in this case 66·6.

To test a lamp it is run at what appears to be about the right brightness, and moved till a balance is obtained on the photometer; the electromotive force on the photometer is then read. Suppose it is 65 volts. The long scale on the photometer is then referred to to see which current curve cuts the 65-volt line under the index. If this does not correspond with the current as read on the ammeter, the lamp is too bright or too dull, as the case may be. This method has some advantages over the first described, as if an ammeter is to be recalibrated it is not necessary to make a new scale. It is also quicker, as the ammeter needle takes some time to come to rest when the magnet box is moved nearer or further from the deflecting coil.

Some makers do not test their lamps on the photometer, as they think it would take too long. This is a great mistake, as the testing can be done very rapidly; one photometer can do 300 a day easily, and while lamps are so very expensive it is certainly worth while to test them properly. If the lamps come out of uniform surface the testing can be done very rapidly, because there is no adjustment to be made. If the surfaces are not all equal, testing lamps in batches against a standard lamp gives rise to serious error, which leads to the lamps being under or over run.

There seems to be a prejudice in favour of a long photometer. This seems to be a form of the same sort of fallacy as leads chemical balance makers to use long and heavy beams, instead of short light ones. The difference between a long and a short photometer is that in one case weak, and in the other case strong, lights are compared, and there can be little doubt that it is easier to compare two strong lights within a given percentage of error than two weak lights. If the photometer is very short there may be slight errors due to the lamp being so close that the illumination of the disc does not vary inversely as the square of the distance from the centre of the lamp. This never occurs in practice, however, and the Methven standard is calibrated in place, so that no errors arise from its being close to the screen.

CORRESPONDENCE.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I may point out that in the case of the field-magnet of a Forbes dynamo rotating round the fixed armature the relative motion is not, as Mr. Snowdon implicitly asserts, the same as when the armature revolves in the ordinary way within the fixed field-magnet, unless, in the former case, the brushes also rotate with the field-magnet, in which case the relative motion of the armature and brushes gives us what is practically, as I attempted to show in my last letter, a circuit of continuously varying area, and thus an E.M.F. is induced in the armature; but if the brushes as well as the armature were fixed while the field-magnet rotated, no E.M.F. would be induced in the armature.

Mr. Snowdon asks what the line *oc'* in my sketch has to do with the circuit.

It is as much part of the circuit as the line *oc*; the whole disc, and not merely the part of it on the straight line between the axis and the brush, gives passage to the current. Obviously the reasoning which applies to one part of the disc applies to another; any number of brushes may be applied to the circumference of the disc, as is done in the Forbes dynamo; but the only advantage gained by doing so is a reduction in the internal resistance. The E.M.F. is unaltered.

There was a slip in my last letter, where I said that the number of lines of force passing through the circuit varied from zero to a maximum and back to zero. Of course the number increases (or decreases) continuously at each revolution. I am sorry that I should have appeared to Mr. Snowdon to be dogmatic. Nothing was further from my thoughts. In

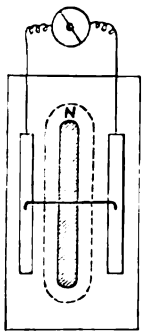
Digitized by Google

point of fact, the statement which he thus characterises was one which I attempted—not, apparently, to Mr. Snowdon's satisfaction—to prove.—Yours, &c.,

Park-square, Leeds. BERNARD P. SCATTERGOOD.

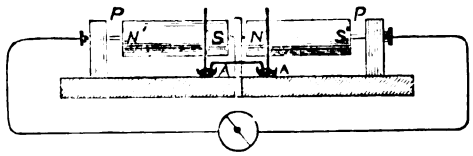
TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Mr. Scattergood did not take kindly to my remarks—which were intended for the vindication of scientific truth rather than to "stigmatise" Mr. Scattergood or anyone else—I enclose a drawing of an experiment which shows simply and clearly that it is possible and desirable to obtain current by the movement of a conductor in a uniform field. N is a wide, flat electro-magnet seen end on. A detached field-magnet of a Siemens machine would do admirably and give emphatic results. A board with a slot is fitted over the core of this magnet. Two parallel troughs are cut in the board, one on each side of the magnet. The troughs are filled with mercury. A wire, W, is the movable conductor, and bridges the magnet by going from one mercury trough to the other. The galvanometer closes the circuit by being in contact with the troughs, as shown. So long as the movement of the conductor is confined to the magnetic area the field may be regarded as infinite to it. In fact, the magnet if made in a curved shape would be a segment of a circle, which, if complete, would be infinite indeed. If, now, the conductor is moved along the troughs a current will be indicated at the galvanometer; and, of course, by having a battery in the place of the galvanometer, the conductor, if floated, will develop a mechanical movement by gliding over the magnet. This I take to be the ideal method of mechanically generating electricity, because the moving wire is continually subject to a maximum magnetic potential, neither increasing nor diminishing the lines of force cut by it. It will be seen that any number of moving wires could be arranged side by side, but the difficulty is to get them in series. Enormous quantity currents may be obtained, but of low tension. I could show at least half a dozen experiments that prove beyond doubt the possibility of producing current under such conditions, but I hope the above will be sufficient to convince Mr. Scattergood. And now for Mr. Thompson. So far from being anxious to show that the pivot arrangement in the experiment shown in my previous letter was practically uninfluenced by the lines of force, I more particularly resorted to it to convince Mr. Thompson of what I believe to be his error, because he laid such stress on his idea that the two fixed conductors were unequally "cut" by the "rotating" lines of force, this fact, according to his view, accounting for the production of current. Mr. Thompson now admits the pivot is practically out of the field so far as the supposed moving lines of force are concerned. I hold that the magnetism is stationary and independent of the molecular construction of the magnet. Therefore, to me, it matters not whether I make contact with the magnet by a pivot or a drum so long as the conductors are fixed, because fixed conductors cannot cut fixed lines of force. It is only the movable conductor that produces the current—viz., the rotating magnet.



Mr. Thompson shows two diagrams; one Faraday's and the other Weber's. I do not remember having seen such an experiment in Faraday's works, but let that pass. In No. 1 diagram, Mr. Thompson treats the disc "simply as a conductor neutral to the action of the force, inasmuch as it revolves with them." But in speaking of the disc as the conductor or generator in No. 2 diagram, he says:—"Here it is evident that the conductor at the centre could cut more lines of force, &c.," so that the rotating disc in No. 2 he evidently regards as the generating conductor. In both diagrams Mr. Thompson assumes the lines of force revolve with the magnets. In both cases the discs are subject to the same inductive influence, and in both diagrams they are affixed to and rotate with the magnets. Now, how can the disc in No. 1 be "neutral" while the disc in No. 2, moving under the same conditions, is the generator? Clearly, Mr. Thompson contradicts himself. I shall be interested to know what grounds Mr. Thompson has for assuming that the current emanates from the wire length *x*, *y*, in his diagram, rather than from the moving disc. An expert electrician without a theory on this subject would be unable to decide which was the generating conductor, so the experiment decides nothing.

Fig. 2 is a design for an experiment which, I think, would throw some light on the question. I have not tried it; but many of your readers will be able to foretell its action, while some, perhaps, may have facilities for putting it to the test. N S are two magnets separately mounted on pivots so as to rotate independently of each other. A thin iron standard goes between them, and supports the pivots. A flange is affixed to each magnet near to the inner poles. Each flange dips into a trough of mercury, and these two troughs are electrically connected by a wire bridge, A. The fact of N and S, the middle poles, being together would cause the lines to be continued throughout the magnets, so that the two would be practically one magnet. There would certainly be some external lines of force at the middle poles, but in comparison



to the extreme poles, N^1 S^1, they would be few. Here, then, we have a system that in all respects resembles a single bar magnet divided at its equator. The lines of force extend from N^1 to S^1, the outer poles, the same as in a bar magnet. Now, let one half of this compound magnet be rotated in one direction, and the other half in the opposite direction, and a current will pass from pivot P along the surface of the magnet by the wire A, and the other pivot P^1, completing the circuit through the galvanometer. But what becomes of Mr. Thompson's rotating lines of force now? Are they crumpled up, doubled up, or torn asunder like bits of string? Or are they infinitely elastic and capable of unlimited twisting? Surely there would be a magnetic catastrophe in this case, if we could only see it. Assuming for the moment that the lines do revolve in opposite directions with the magnets, how is the current generated in this experiment? Where is the fixed conductor that can even remotely be supposed to be cut by any "moving" lines of force? It is impossible to explain the action on the rotating lines of force theory. How different if we seek for an explanation by regarding the lines of force as a fixed element. Under such conditions it matters not which way each half of the magnet revolves, and its own electric conductivity is enough to account for the production of current as its molecules cut the fixed magnetism. Mr. Thompson trips me up somewhat sharply by asking "How a quality such as conductivity can itself be a cause of action?" We know that oxygen is not the cause of animal life, and we know equally well that animal life cannot exist without oxygen, and it would not be wrong if we were to say that animal life exists by reason of oxygen. By the same reasoning, although conductivity is not the cause of electric action, it is an essential quality for the manifestation of its effects. I know not which is of the more importance, the cause itself, or that quality which allows its effect to be made evident to us. Therefore to say that a current exists by reason of electric conductivity—inasmuch as it does not exist without this quality—is, I think, sufficiently logical for our purpose. Mr. Thompson asks me to explain, on my theory, how current can be produced in two discs on the same axis. If you, Sir, can find space, I will do so in my next letter.—Yours, &c.,

E. L. VOICE.

THE ELECTRIC LIGHT COMPANIES.

As the season of annual meetings advances we are enabled to form some idea of the financial condition of the Electric Light Companies and of the prospects before them in the coming year. On the whole there are reasons for hopefulness all round; and if the business of the Edison and Swan Company, whose yearly meeting we reported in our last week's issue, be taken as an average example of what the companies severally have been doing, their shareholders may very well be satisfied with the progress Electric Lighting is steadily making. Under its new management this company has been improving, and the year just reported upon shows a business profit of £16,221, a sum which, although at present not available for anything but paying off arrears of debt, is large enough to give promise of dividends at no very distant date. The doleful particulars relating to Electric Light Companies furnished by *Burdett's Official Intelligence*, and reprinted in our "Notes" of last week, reveal chiefly the state of affairs down to the middle of last year, since which time they have taken a turn for the better, and to such an extent that a dividend-earning period may now be confidently looked forward to.

We are, however, far from wishing to minimise the gravity of the figures to which we have just referred. They indicate that some of the companies were earning very little, and that others were scarcely doing more than paying their way. This is no doubt very discouraging to investors; but it may be well to point out here that the figures only relate to Companies, and that private firms are doing the self-same class of business with a fair return for their outlay. The cause of their comparative failure hitherto in the case of Electric Light Companies is not far to seek. They have expended vast sums for patent rights, and have competed with each other for business at unremunerative prices. Despite the prohibitive legislation of 1882 there is a great deal of Electric Lighting being done, and the area of operations is rapidly enlarging. In reality, the business, considering how young it is, has made wonderful strides, and if it does not pay, the fault is not with the business but the people who carry it on. Here, for example, is a company making a profit last year of over sixteen thousand pounds, and this on transactions by no means gigantic. Any private firm of moderate dimensions—such a firm as, indeed, would be quite large enough to do twice or thrice as much work—would be amply satisfied with the profit just named. This fact is worth emphasising, because if private firms engaged in the business of Electric Lighting are unable to command their legitimate profits, it must be because their competitors are struggling for business which in the aggregate is considerable, but the profit on which is reduced to the finest point. Our contention is that the Electric Lighting business is flourishing, but that it cannot possibly pay the number of people engaged upon it, or, more correctly, the amount of capital invested in it.

That the capital of the Companies was far too large is proved by the wholesale reductions which took place a year or two ago, and which may possibly have to be repeated. The capital is not an available asset, and, worse still, it is not a working capital. In both these respects the private firm has greatly the advantage of probably every Electric Light Company in existence. It is perfectly astounding to hear these Companies talk of their respective capital as half-a-million or more—a capital out of all proportion to any prospective return that they could ever hope to earn. For it must be remembered their capital represents not money that can be employed for promoting and extending business operations; it has gone to pay for patent rights and for defending them in Courts of Law. These patents appear to have been paid for on a scale which, had they been certain to supersede all existing railroads, or render useless all existing telegraph wires, or to extinguish every gaslight in the kingdom, could hardly have been higher. Except and beyond the value of these patents for which such fancy prices were paid, most of the companies are poor, and have to save themselves becoming poorer by defending the rights they own or acquiring others which threaten them. In his speech at the meeting of the Edison and Swan Company last week, the Chairman said that after some considerable experience he had arrived at the conclusion that any one who stakes his money on a patent is a fool. He presently explained that he meant "until the validity of the patent has been established." He might with more reason have said "until the value of the patent has been ascertained." Patent rights, like patent medicines, are never quite safe unless they are worthless.

The craze which possessed the investing public a few years back appears to have not yet been exorcised. Every now and again there is put on the market some mysterious discovery which is to give to Electric Lighting industry the fillip it is supposed to be in need of. In reality, it needs no such artificial aid; but if it did, the very worst that can happen to it will be a revival of the mania for buying patent rights at fabulous prices. As a rule these discoveries, like the one we commented upon last week, are worth just as much as they will fetch to the vendors, and exactly that much less to the buyers. We have said this many times before, and

Digitized by Google

we repeat it again just now, partly because the warning is needed, not for the general public only, but for the shareholders in existing Electric Lighting Corporations. Unfortunately promoters are never wanting to take up any new scientific scheme which a non-scientific press can be induced to back up, and an ignorant public to swallow. The proverbial, and often quite ingenuous, enthusiasm of the "discoverer" is a quite contagious influence in the transaction. As we are penning these lines a letter reaches us from the States, inviting us to introduce the writer to "your people"—meaning the English investing public—to take up his idea of telephony, which will enable us to telephone clearly and distinctly through "3,000,000 miles of submarine cable." The idea has a basis of truth but a superstructure of nonsense. What the truth is does not signify, for it is not new and it will not do. But the nonsense will or may do a great deal. "The direct route core will reproduce *instantaneously* from the narrow spout through which the current goes, [just] as, for instance, water with a given force will obtain greater velocity through a narrow spout, as compared to a wider or larger one. The outer surfaces [of the inventor's wire] will take up all inductive adjacent sounds (air waves), and by their spiral velocity will be thrown off the wire and return to the atmospheric undulatory movement." Now, this is the sort of thing that fetches; we seem to be reading something from *The Times* newspaper; and it does not surprise us to learn from another part of our amiable correspondent's communication that he is already doing business in the United States, and is prepared to dispose of his "rights" in the British Isles. Nor would it surprise us very much if British money is some day forthcoming to buy this man at his own valuation. All that we can do is to warn the public off new inventions unless they understand them, and the companies off patent rights unless they want them and can get them a bargain. What the Electric Lighting Companies have to do is to push their business vigorously, and to conduct it so well that their reputation will outlive and outweigh all the patent rights they now, or ever can, possess.

PROF. FORBES' DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Snowdon in his last letter complains of not having received the information he sought, and on reference to his inquiries, published in yours of the 1st ult., I find he says, "I can understand that all will be well if the rings of magnetic force encircling the exciting coil" (of Prof. Forbes' dynamo) "are held *quasi* fixed by the current in the coils, but if that were so it would answer as well to rotate the coil instead of the armature." Now, the whole of the correspondence on this subject has turned on the question whether the field is fixed by or independent of either the coils or the magnet, as the case may be. Mr. Snowdon and Mr. Voice both maintain its independence, while I as stoutly uphold the reverse. There has, so far as I can see, been no solid objection brought against the theory of a fixed and dependent field, but only an endeavour to establish the other, which has not been too successful. In answer to the latter part of Mr. Snowdon's inquiry, I do not see why he should not get current under the conditions mentioned, but it would be very feeble by reason of the absence of the core. Mr. Snowdon is possibly right in assuming that the disc of the machine in question would tend to carry the field, but this action, I maintain, would be resisted by the field itself, and would be of the nature of a permanent strain in giving distortion, not motion.

To produce resultant force of an electric nature, I maintain that it is necessary to oppose the mechanical action given to the molecules of the armature when revolving by a field force of magnetic nature, on very much the same principle that mechanical forces brought into collision may be made to produce such physical forces as heat, sound, &c. In this I differ from Mr. Voice, who assumes that it is possible to produce such resultant phenomena as dynamic electricity without the interposition of a reactive agent.

From careful perusal of Mr. Snowdon's last and previous letters I understand him to maintain that the armature of a machine of the type under discussion would cause the field to revolve, and that the field in its course is first opposed to the resistance of the field-magnet core by reason of the induced currents it generates therein; that this opposing action causes a reduction in the velocity of the field, which now reacts on the armature that is passing it at a higher velocity. If this is a correct statement of his theory there will be little difficulty in showing its fallacy; but first I may remark that Mr. Snowdon's endeavour to account for resistance in the core of the field-magnet by heat produced by the direct action of the field is not very satisfactory. Mr. Snowdon knows well that the Foucault currents are by far the most potent, if not the only cause, and that any heat developed as he suggests would be much too insignificant to give, in his theory, the necessary reaction for the powerful current generated. But I will treat Mr. Snowdon's theory on more definite grounds; I will assume that the magnet core does oppose the necessary resistance, and that the consecutive actions are as stated.

We are given to understand that the field as a whole is impelled by the revolving armature or disc. How, then, about the magnet core? If the armature passing the core is the same in effect as the armature and core revolving in opposite directions, would they not both possess the same property, and exert equal but opposed strains on the field? Where, then, would be the field's motion? Of course, something must give, and according to Mr. Snowdon the giving would be in the molecules constituting the armature and core; but if the impelling action of the forces (treating the armature and core as two bodies revolving in opposite directions) on the field molecules is dependent on the power of the induction effected, it will be evident that the same result will be arrived at, as the resistances of the armature and core to induction will be equal and opposed. If Mr. Snowdon's hypothesis were true, it would not be possible to return as useful effect in the armature of this machine more than 50 per cent. of the original energy imparted. I wish, Sir, to correct an error I made in my last letter, to the effect that velocity would vary as the square of the radial distance. I had in my mind at the time the total effect of the varying velocities on the molecules of the conductors in question, which would of course vary in this ratio. This mistake does not, however, affect the main question at issue, and the measures set forth for the course of current will still retain their force. I may also remark that the sentence relating to a magnetic field at the end of that letter should have run "and it is the ether atoms or molecules under the influence of velocity, &c.," and not force as stated. Perhaps, to meet the alternative theories of a magnetic field, I ought to have said "under the influence of velocity or strain, &c."—Yours, &c.,

N. G. THOMPSON.

4, Queen Victoria-street, E.C., Aug. 16th, 1887.

THE OERLIKON DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your notice of the Oerlikon dynamos you question the advantage of threading the armature wire through holes punched in the iron, because a path is afforded for the lines of force to cross from pole to pole round the periphery of the armature without passing through the windings. As, however, the iron between the edge of the holes and the outside of the armature is only half a millimetre or less in thickness, I think you will agree with me that the number of lines that take this path instead of the shorter and easier one through the unsaturated mass may be neglected. I cannot understand how the iron of the armature can under any circumstances "tend to increase the

Digitized by Google

magnetic resistance of the whole of the field iron." Doubtless there is some error here, as there is in the statement that the machine was designed for an output of 50 horse-power when the electrical return is 115 volts and 440 amperes. With regard to the magnetic circuit being rather long, I can only say that I have been under the impression that in machines of this type it is short. As to the leakage across the horns of the field-magnets, I think it may be neglected in a machine that has a magnetic circuit wholly of iron except for the very small air clearance between the smooth iron armature and the iron of the field-magnets.—Yours, &c., C. E. L. BROWN.

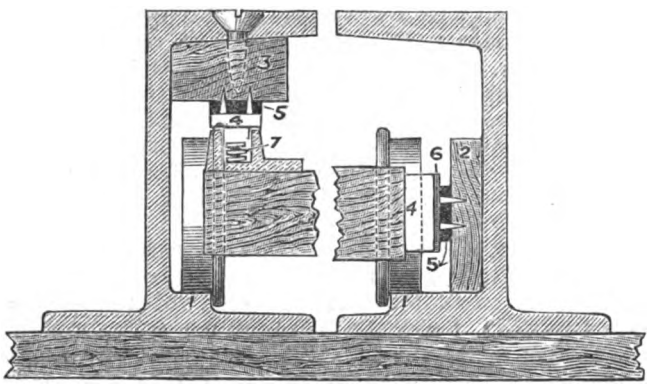
Oerlikon bei Zürich, 15th August, 1887.

[Mr. Brown must surely be aware that the magnetic resistance of iron increases with the magnetisation. Consequently, if a number of lines traverse the field-magnet circuit without cutting the armature coils, it is obvious that such lines merely tend to increase the magnetic resistances of the whole of the field iron. However, we have no wish to lay any stress upon the point, especially as Mr. Brown points out that the rim is only 0·5 mm. in thickness, and we are glad also to have a correction of the misprint of 50 horse power instead of 60 horse-power.—ED. *E.*]

THE BIDWELL ELECTRIC RAILWAY CONDUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed your description of Mr. Bidwell's "invention" for "improvements in electric railway conduits," and express my agreement in your remarks upon the design by sending you an extract from one of my earlier blue books.



The drawing is exactly as printed; two methods are shown in one view.

Bidwell's (?) detail for making the upper part of the channel removable, and his method of connecting the collector with the car are also shown in other sketches, which I can send you if necessary.—Yours, &c., M. HOLROYD SMITH.

Halifax, Aug. 16, 1887.

Extract from Specification.

"Fig. 14 illustrates a section of trough wherein a ledge of the lower portion of the trough serves as rails for the wheels of the trolly. The position of the conductor bands 5 is changed, in the one case being attached to the insulating block 2 at the side of the trough, in the other case the conductor bands are attached to the insulator block 3, and in each case the collector 4 is kept in contact with the conducting bands by means of the blade or spiral springs 6, 7. In these cases two bands may be used, one for the flow and one for the return, or only one for the positive, the return being by way of the wheels of the trolly through the metal of the channel."

"ELECTRO-DEPOSITION."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On reading the review of my work on "Electro-Deposition" which appeared in your last issue it was impossible for me not to recognise, in its style and matter, the authorship of a similar review which appeared in *Nature* on April 1, 1886. Nor is it difficult to trace in both critiques the hand of *a competitor*, by which I mean one who has himself written a work upon the same subject. When comparing these two reviews, the one which appears in your own journal reads like a parody upon the one in *Nature*. The same references, the same quotations, the same terms, the same objections or complaints, and the same commendations occur in each; but occasionally a slight modification of terms is adopted in your version, so that it may not read quite like an exact copy of the one in *Nature*. In both of the reviews referred to, the critic has been pleased to represent me as a kind of floating "electro-plater"—one who has "spent a *large* (!) period of time in manufactories of electro-plate," or, as he puts it in your contemporary's columns, "spent a *long* period of time in electro-plate workshops." Now, if I am not mistaken in my conjecture as to the authorship of these reviews, the writer must have known that in my professional capacity of consulting electro-metallurgist, I must necessarily visit from time to time numerous establishments to impart such advice or instruction as might be required from one whose experience in electro-deposition has extended over a period of nearly half a century. To style me an "electro-plater," in the ordinary sense, is, therefore, somewhat misleading, as your reviewer should know that besides being author of a long series of works of a more or less useful kind, I am also one of the oldest scientific journalists in this country.

Having called attention to the identity of the two reviews in question, I will now, with your permission, refer to the complaint that my book "is seriously deficient in the chemical, the thermo-chemical, the electro-chemical, and voltaic principles of the subject." Now, the reviewer must have known, from the title of my work, that it was intended to be a "practical treatise," and as such the elementary matter to which he refers should have no place, in my opinion, in a book intended chiefly for practical readers. Moreover, I had heard so many complaints from practical men, that Gore's book on "Electro-Metallurgy" contained "too much scientific and useless experimental matter" to render it of any service to practical operators, that I determined not to fall into the same error. Knowing my *clientèle* and their requirements well, from the abundance of correspondence which has reached me from all parts of the world acknowledging the usefulness of my former work "Electro-Metallurgy Practically Treated" (Weale's series), now passing through its ninth edition, I purposely avoided entering deeply into the theoretical part of the subject, leaving the readers to seek such knowledge from works specially devoted to chemical and electrical instruction.

On page 80 of my book (to which your reviewer refers), the chapter (Chapter V.) opens as follow, the words in italics having been designedly omitted by him in order, I presume, to pervert my actual meaning:—"*While it would be beyond the province of the present work to enter deeply into theoretical considerations*, it is necessary, in the present advanced state of electrical science, that both the student and practical operator should be acquainted with the principles and laws which govern the development of electricity, &c." The object of mutilating this paragraph by leaving out the words in italics speaks for itself; but surely such a method of quotation for the purposes of adverse criticism cannot be too highly reprehended. Again, the reviewer disregarded the concluding sentence of the same paragraph, which runs thus:—"For a full knowledge of the laws of electrical science the reader is referred to standard works on electricity," &c.

I was somewhat amused at the cunning with which the critic connected my remarks upon "mystery gold"—an alloy of copper, platinum and silver, and manufactured specially to defraud pawnbrokers—with a method I had described for gilding "cheap jewellery"—that is, articles made from brass or gilding metal. The latter class of articles, being retailed at only a few pence each, are not usually confounded with what is known as "spurious gold," and a mere "dip" in the gilding bath on the most economical terms possible would be the only conditions under which such work could be gilt at a profit. Although I appear to have shocked your critic's high sense of morality by stating that I

Digitized by Google

had found a *copper* anode most advantageous for gilding goods of this description, I must adhere to my statement and leave my censor to recover from his perturbation as best he may.—Yours, &c., ALEXANDER WATT.

London, August 16th, 1887.

[We have inserted Mr. Watt's letter, although we do not approve of the growing habit of authors criticising reviewers. We are absolutely ignorant as to the personality of the *Nature* reviewer, nor are we to blame if Mr. Watt's book was reviewed in our contemporary in 1886. His publishers did not forward us a copy for review till the middle of the year 1887, and we in our innocence imagined the work only recently published. It by no means follows that because two reviewers condemn or praise similar portions of a book that the two reviews are by the same hand. If the reviewers are competent they are compelled to condemn the same faults and praise the same good features. As a matter of fact a considerable portion of the review of Mr. Watt's book was deleted editorially owing to the exigencies of space, and had the review in its entirety gone in, Mr. Watt's opinion as to similarity might have been modified. Mr. Watt really uses his imagination to make a covert attack on the work of a "competitor," and we think has in this letter laid himself open to retaliation. The work of Mr. Watt has been and is highly appreciated, and in our estimation he should welcome what he terms adverse criticism, if only to enable him to make future editions unassailable.—ED. *E.*]

THE MAGNETIC FIELD OF THE THOMSON-HOUSTON DYNAMO.

The figures illustrating this paper and the comments thereupon are taken from an article by Mr. Carl Hering in our contemporary, *The Electrician and Electrical Engineer*, of New York, where they formed part of a more extensive contribution to the subject. It happens, however, that the majority of the machines whose magnetic fields have been examined by Mr. Hering were of old-fashioned type—as the Edison machine with 12 magnet limbs—or else have obtained no footing in this country, so that the chief interest in the paper lies for us in the investigation of the Thomson-Houston dynamo. It may be taken for granted that every one has already agreed that this machine is magnetically of extremely bad design, and a certain authority has even expressed surprise that the machine can be got to work at all. After examining the diagrams we should say that his astonishment will be considerably increased. Yet we know that the Thomson-Houston machine is, at least for arc lighting, a thoroughly practical success, and we are not aware that any complaints are made as to its efficiency. It is, of course, true that mere leakage lines do not imply a corresponding increase of exciting power until the saturation point is approached, but as arc light machines, working as they do on the horizontal limb of the characteristic, such lines must still represent a certain waste of E.M.F. in excitation, even if they do eventually pass through the armature.

Mr. Hering thus describes his method of examination:—

The exploring needle was an ordinary short, light, compass needle, strongly magnetised, and loosely supported on a pivot. While the dynamos were running and the magnets fully excited, this needle was moved about in the space surrounding different parts of the magnets and the machine frame. If the case containing the needle be turned so that the needle is always perpendicular to its pivot, thus allowing it to turn as if on a ball and socket joint, the needle will take the direction of the lines of force in this space. By moving it systematically all around the different parts of the machine, and by plotting the direction of the needle on outline drawings of the machine, the directions of the lines of force may be readily indicated. To explore the curved paths of the lines of force the needle may be held near to any particular part of the frame and then moved continually in the direction in which the farther end points—that is, as the direction of the needle changes, the direction in which it is moved must be changed so as always to conform with that to which the needle points. The path which it describes will then be that of the particular line of force. In this way the curvature and the two terminals of an external line of force can be determined and plotted with all due accuracy, as the needle is always a tangent or short cord to that curve, and where the needle points directly to the iron when held closely to it, it indicates the point where the line enters or leaves the iron. By shaking the needle to cause it to oscillate, a rough approximation can be obtained of the intensity of the field or the number of lines of force at different places. Great care should be taken not to move the needle too fast, as the lines of force in some machines make such short curves that the needle is demagnetised and even reversed in polarity before it has time to turn on its pivot. It is necessary, on account of this possible reversal of the magnetism, to test frequently its polarity at one of the machine poles, otherwise very queer and conflicting curves may be obtained.

It will greatly facilitate the examination and plotting of these curves to remember that every line of force appears to make a closed curve which encircles the wire through which the exciting current flows. This will also enable one to interpolate the probable return paths of the lines in the iron where their presence cannot be ascertained by means of a needle otherwise than by their external manifestations. All lines which do not pass from the pole-piece to the armature core, and are therefore not cut by the armature coils, are wasted and represent leakage.

In the accompanying diagrams the probable return paths of a few of the lines of force in the iron parts have been indicated, and it is believed they are correct. The drawings may not in all cases represent the exact proportions of the frame, as they are copied from mere rough note-book sketches.

The field around the Thomson-Houston machine, shown in Figs. 1, 2, and 3, proved to be one of the most interesting, some of the curves being of a very peculiar nature. The magnetism was so intense in several places and the lines made such sharp turns that the exploring needle was repeatedly reversed in polarity during the examination, thus giving absurd results. It was not until the needle was repeatedly tested for polarity, and all results obtained with a reversed needle discarded, that any conclusive results could be obtained. The test was furthermore rendered difficult at first by the fact that the direction of the lines of force could not be tested in one plane only as in the other machines, as they curved around in different planes in such a way as to make it difficult to represent their courses on the plane of the drawing. In order to be sure that the results were correct the writer recently repeated the tests very carefully on a new 30-light arc machine, and obtained the results shown in the figures, which are believed to be substantially correct.

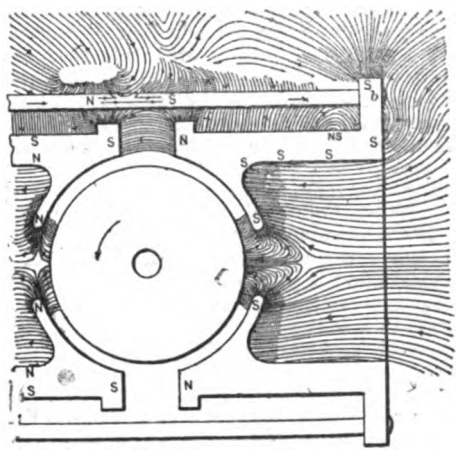


Fig. 1.

Figure 1 shows more than half of the vertical cross-section through the centre, taken perpendicularly to the shaft. The coils are wound around the large, hollow cast-iron cores which terminate at the armature and at the ends of the machine, one of which is shown complete. There is a round opening in the thin shell which embraces the right and left hand sides of the armature. The intended yoke-piece consists of a series of horizontal, round, wrought-iron bars, two of which are shown, one above and the other below the armature. As in the Van Depoele machine, there was a very strong leakage from the magnets to the yoke-piece, especially at and near the ends of the pole-pieces, showing that many lines of force were magnetically shunted around the armature, and were therefore wasted. A neutral point was found near the right hand end of the core, as shown. Immediately above the bars of the yoke-piece a strong field existed which showed the same polarity as that between the yoke and pole-piece, as indicated by the arrows, showing that these yoke-pieces had two strong poles one above each of the pole-pieces, but of opposite

Digitized by Google

polarity to the latter. Immediately above this field and represented by an open space, the needle exhibited that peculiar state of unstability, indicating a point of deflection, while above this space it again had a definite and decided direction. In this space, left blank on the figure, the lines were found to be perpendicular to the plane of the drawing, as is shown more clearly in Fig. 2, which is an enlarged vertical cross-section taken through the north pole-piece perpendicular to the bars of the yoke-piece. As shown in this figure the lines passed from the pole-piece into the yoke-piece on all sides, while the others from the pole-piece pass out into the air between the bars, thus forming above the bars at about the relative distance shown, a point of deflection having four poles, similar to that in the Edison and Weston machines.

Referring to Fig. 1 a peculiar deflection of the lines was noticed almost directly above the south pole-piece, which was somewhat similar to that observed in the Van Depoele machine. It is possible that this was due to another point of deflection existing in the iron, as indicated in Fig. 1, with four or possibly six poles, but these curves in the iron itself are probable conjectures only. A similar deflection was noticed a few inches to the left of this point.

In moving the exploring needle vertically above the north pole-piece, it was found to turn abruptly through almost 180deg. a few inches above the yoke-piece, as shown by the arrows, while nearly above this there was a deflection similar to that in the Van Depoele machine. This was found to be due to a point of deflection existing between the bars, but above them, and is shown more clearly in Fig. 3, which represents a portion of a section like Fig. 1, but between the bars. This point was clearly indicated by the needle, and assists in connection with Figs. 1 and 2 in explaining some of the peculiar curves noticed above that part of the yoke-piece which lies above the pole-pieces in Fig. 1.

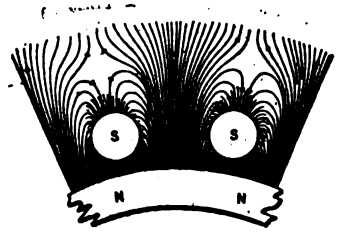

Fig. 2.

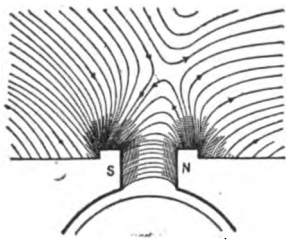

Fig. 3.

At the right hand end of the core the usual strong pole was found. A peculiar curving of the lines was noticed at *b*, where the rounded projections of the wrought-iron bars passed through the flanges. A possible explanation of this is that the cast-iron flange is over-saturated to a greater extent than this projection of the wrought-iron bar, which, therefore, attracts the lines.

Following the surface of the core to the inside or hollow portion, a weak south pole was found to exist on the cylindrical surface, while on the interior flange embracing the armature the south pole was found to be very strong, the lines from it passing out through the open end. By placing a small needle very near the revolving armature and in the opening in the iron it was found that many of the lines from this south pole entered the armature. From the general principles underlying all other dynamos it would be supposed that the polarity of the pole-piece embracing the right hand half of the armature was the same in all parts, but it appears from the external lines of force which could be examined that this is not the case with this machine, as there is a strong north and a strong south pole on different parts of the same pole-piece. Careful and repeated examinations with the exploring needle on the same and on different machines clearly shows this peculiar disposition of poles to exist.

Near the opening, through the centre of the core, was another point of deflection with four poles, which in some machines was found to be very near the armature, as shown on the left hand side, while in others it was located several inches from the armature as shown on the right hand side. The lines of force at this point were very intense, and their curved directions are very decided ; for this reason it was found that a very short needle had to be used and that it had to be moved about very slowly to prevent it from having its polarity reversed before it could respond to the change of direction. By moving the needle rapidly from the armature through this point of deflection, its polarity can readily be reversed, and it will then point in the same direction as it did before passing the point, thus making it appear as if there was no point of deflection. Moving the needle towards the armature will not reverse it so readily, as these curves are less abrupt. The lines of force at this point appear to oscillate very rapidly, which is probably due to the pulsating character of the magnetising current. It is quite probable that the curves shown in all these figures would change very much with different degrees of saturation. A careful study of the curves of each machine at regularly increasing degrees of saturation might lead to a determination of the best proportions and shapes of the iron parts.

Fig. 1 is a good illustration of how not to proportion the parts when the best economy of magnetisation is desired. At the same time it must not be forgotten that the energy used to excite the magnetism is for the best machines only a few per cent. of the whole output, and that, therefore, any improvements in the frame that would economise magnetism would only lessen this already small fraction, and possibly in some cases economise material. Other conditions may be of so much more importance as to make an increase in the economy of magnetism of little significance in comparison. The fact that the Thomson-Houston machines are used in such large numbers, shows that great economy of magnetism is not one of the most important points about a machine.

From the nature of the fields surrounding a dynamo, as shown in the figures, the following general deductions may be made :— That machines exhibit the following magnetic properties : Free north and south poles, neutral points of two different polarities, and points of deflection. The latter exist in the external fields, but may possibly exist also in the iron itself ; they generally appear as four curvatures of the lines of force towards and receding from one point, and are in that case enclosed by four free poles and four neutral points of alternately opposite polarity.

OKONITE.

Okonite is an improved variety of a rubber composition which has been long and extensively applied in America as a waterproofing material, and for other purposes for which rubber fabrics are generally employed. It appears to be peculiarly well adapted to resist the American climate, and coats waterproofed with it last a very long time. The idea occurred to Mr. J. J. C. Smith, of Passaic, New Jersey, U.S.A., that this material might be also used for covering electric conductors ; but his first experiments made in this direction were unsatisfactory, the original material not being sufficiently waterproof, besides lacking certain mechanical qualities which are essential for perfect insulation. Mr. Smith thereupon set to work to improve the material by mixing it with other ingredients, and of each composition large sheets were made and suspended by the four corners. Water was then poured into these sheets, and the rate of leakage observed. Having in this way found that composition which is most impervious to water, Mr. Smith concluded that it would also be the best insulator, and began to apply it for that purpose. The precise constitution of this material is a secret, but the inventor states that it contains 38 per cent. of fine pure caoutchouc and 62 per cent. of some natural hydrocarbons, oxides, and silicates. The composition is applied to electric conductors in the following way :—It is first rolled out upon sheets of stout tinfoil, and the two surfaces are made to adhere slightly by the pressure of the rollers. These compound sheets are then cut into strips of slightly greater width than required to wrap round the wire with a longitudinal seam. The strips of okonite with their tin backing are then joined end to end, so as to form one long continuous band, which, for convenience in the subsequent process, is coiled upon a reel. The tin backing, however, was not the first employed by the inventor. Originally the backing was of woven fabric, and sufficient pressure was applied to make the okonite enter into the fabric so that the two surfaces adhered firmly. These sheets were drawn over a large metal cylinder and their edges joined. The continuous tape was then produced by making a spiral cut over the surface of the cylinder with a revolving knife. The wire to be covered is also wound upon a reel, and both tape and wire are simultaneously passed through a machine, by which the insulator is laid on longitudinally instead of spirally. The principle of covering wire with an insulating compound laid on longitudinally instead of spirally is not new in itself, having been applied, as early as 1848, by Messrs. Barlow and Foster, who placed the wire between two heated fillets, made to adhere to each other in two longitudinal seams by passing between two suitable rollers. Mr. Fleetwood, in his recent paper read before the Society of Telegraph-Engineers and Electricians, also mentions a machine, patented by Mr. John Lewis

Digitized by Google

Ricardo about the same time, which consisted of a pair of grooved rollers, through which were passed several wires placed parallel between two fillets, the action of the rollers being to bite nearly through the gutta percha and allow of the wires so covered being easily separated. These early attempts at covering with longitudinal seams proved unsatisfactory, however, the seams in many places opening, and thus exposing the conductor. This drawback has been overcome by Mr. Smith, partly in consequence of the nature of the compound, which welds much better than gutta percha, and partly because the machine which lays the tape round the wire draws it up very tightly, an operation which is rendered possible by the backing employed with the tape. Mr. Hannan, who represents the inventor in this country, is so confident of the mechanical and insulating properties of okonite that he considers it possible to utilise these cables when simply drawn through existing sewers without any protection whatever, and for indoor electric light installations to embed them in the plaster without wood beading or other protection. The tests by Dr. Hopkinson above referred to included also the measurement of inductive capacity, insulation, and the absorption of residual charge in pieces of wire not mechanically abused. The capacity was measured by charging a known length of the conductor to a known potential, and then discharging it through a ballistic galvanometer. From these measurements, and from the dimensions of the conductor and its insulation, the specific inductive capacity of the material can be deduced. It was found that the specific inductive capacity varied between 4·444 and 4·849, the mean being 4·6, which is very nearly the value generally given for gutta percha. The insulation was tested by immersing about 2,000ft. of wire in water, then charging it to a known potential, and measuring by means of a quadrant electrometer the rate at which the potential fell during a given time. Obviously the rate of loss of potential per second, multiplied by the capacity of the wire, is inversely proportional to the insulation resistance, if the latter is independent of the potential employed. This point had previously been ascertained by making the tests with 375, 50, and 3 Clark standard cells. The temperature of the conductor was assumed to be the same as that of the water of the bath, and the following table gives some of the results obtained :—

2,000ft of ·85mm. wire measuring 2·96mm. over the insulation.

Temperature in Centigrades.	Insulation Resistance per Statute Mile, in Megohms.
30·75	2,238
28·0	3,344
25·7	4,475
22·5	5,387
17·8	8,311
13·2	10,389

1,950ft. of 1·6mm. wire measuring 4·4mm. over the insulation.

Temperature in Centigrades.	Insulation Resistance per Statute Mile, in Megohms.
28·5	4,553
24·5	6,395
17·6	12,209
15·15	17,910

It will be seen that the insulation resistance decreases considerably with an increase of temperature; but even for comparatively high temperatures it is exceedingly good. The absorption of residual charge was found to be so unimportant that it need not enter into consideration in any practical application of these wires.—*Industries*

THE SUPPOSED "NEW FORCE."

BY DR. SHEITLE.

The editorial remarks in *The Electrician* of July 8th, on the supposed "new force," require some comments from me, and in making such, perhaps the better course will be for me to explain in a few brief words the theory I have long held with regard to the relations which exist between gravitation and magnetism, and the method I have adopted experimentally to test its value. By such means I hope to prove the place which radiant heat holds in relation to the phenomena observed by M. Thore.

My theory is briefly as follows :—

1. That the earth's mass is permeated by currents of ethereal matter which take two opposite directions, *i.e.*, from and to the centre of the earth.

2. That the currents which pass from the earth's centre are the more immediate outcome of the attraction of the sun and moon, each of those bodies by its axial rotation originating forces of which its own mass is the centre.

3. That the currents which take the opposite course, *i.e.*, towards the centre of the earth, are the result of the earth's axial rotation.

4. That the currents affecting the earth from either source, being dependent upon the *mass* of the earth, are equal, opposite, and imperceptible, except when they are interfered with by some impressed force.

5. That the motion of the sap in vegetable life, the motion of the blood or nutrient fluid in animal life, constitutes displacement of matter, and in common with the mechanical motion of a stone, the motion of a pendulum, a local rise of temperature, a chemical change, &c., &c., gives a new direction to the force so far as the particle moved is concerned.

It will be perceived that this theory does not differ from that now held with regard to gravitation except in one very important particular, viz., *the existence in every rotating mass of two opposite currents of highly attenuated if not absolutely ethereal matter.* That such currents do exist I believe any impartial observer will admit when the experiments which I have conducted are duly considered. Moreover, in the present state of our knowledge the cause of gravitation is declared to be altogether unknown, if not unknowable. Under my theory all mystery vanishes, for all the phenomena which pertain to the life of the universe can then be directly traced to the mode in which dissimilar forms of matter are acted upon by current forces, which permeate and sustain them in their natural condition.

The plan I have followed to test how far facts support the above theory may also be briefly stated, and is as follows :—

1. I ascertained the magnetic character of the arterial and venous blood corpuscles, and proved* that the arterial blood corpuscles are paramagnetic to the corpuscles of the blood in the venous state—a fact of no inconsiderable importance when it is recognised that the arterial corpuscles have the power of stimulating the nerves to a healthy vital action, whilst this property is entirely removed from the venous corpuscles.

2. I investigated the character of magnetic force in bar magnets,† and have proved—(A) That the equator is always oblique ; (B) That when two magnets of the same size are placed together end on, the polar line in each is removed from its previous position a little distance short of the pole end, and in the case of two magnets of equal power is found along the line of contact ; (C) That when two poles of the same size are placed near to each other, and the position of the filings which mark the central quadrangular space is carefully observed, these lines are always uneven. Phenomena 1 and 3 are suggestive of motion being established by unequal couples ; whilst No. 2 shows the readiness with which the polar forces of two magnets are displaced and converted into a single pole absolutely at the line of contact.

3. I have been conducting the experiments to which the editorial note in *The Electrician* refers with the object of showing the cause of terrestrial magnetism. I believe these experiments show : 1. That the axial and orbital motions of a planet are primarily dependent upon the mode in which the mass refracts, and then deals with currents of highly attenuated if not ethereal matter, as such matter is drawn through it by the attraction of the sun. 2. That the magnetic poles are the direct outcome of these lines of highly attenuated matter being brought to foci or points, and consequently—3. That magnetism and gravitation are only different names for the same form of motion.

With the foregoing preliminary remarks I shall now proceed to state the nature of the experiments, but in order fully to understand the significance of the phenomena evolved it is necessary that my method of investigation and the apparatus used should be fully described.

The accompanying drawing (Fig. 1) gives a good general idea of the apparatus, and may be readily understood by reference to the letters affixed to different portions. The heavy circular table T, 2ft. 6in. in diameter, is fixed to the floor by means of brass screws attached to each leg. On the upper surface is a raised inner circle 21in. in diameter and 1in. high ; round this is fitted a flat wooden ring 1in. thick, which extends to the edge of the table ; another slab of wood 23in. in diameter is tightly fixed down to the central raised portion, so forming with the lower portion a groove in which the flat ring can work easily. To one side of this ring is attached a wooden arm, U, for supporting the lamp stand and scale ; the latter extends through 90deg. on either side of the zero point, the radius being 36 inches. By means of the ring the lamp and zero point

* Vide *Proceedings* of the Royal Society, No. 157, 1875. † *Ibid*, 1879.

Digitized by Google

of the scale can be adjusted to any part of the circumference of the table without disturbing any object which after suspension had come to rest.

Upon the upper platform of the table is a carriage for the magnet G. This is so constructed and placed upon rollers, R, that it is capable of being moved round the suspended objects, the distance from the centre being kept by a central perpendicular pivot or trunnion H, which is embraced by a projection from the carriage just named, and supplemented by another adjustment by means of which the base board of the magnet slides either to or from the centre. By this movement the magnet could be adapted to objects of various sizes.

The coil of the magnet M is placed horizontally in a wooden bracket, or clamp, which also turns upon a central pivot, enabling the axis of magnetic force to be directed to the centre, or to one or the other side of the suspended body. The coil is fixed in position by a brass cap screwed down to the wood on either side.

Accuracy with regard to the axis of magnetic force in relation to the centre of the suspended body is secured by means of six strands of fine silk, which are strained across the aperture of the coil next to the suspended body, one across the centre of the field perpendicular to the axis, and one at a distance of half an inch on either side; these strands are crossed horizontally by three other strands arranged in the same way. A movable brass cap, with central aperture of the same size as the tube in the coil, is crossed by similar strands of silk, and fitted over the other end of the coil. By this arrangement for sighting, coupled with the universal adjustment provided by the torsion head, which will be described, the filament suspending a body in the magnetic-field can be accurately adjusted so as to be in exact line with the axis of the magnet at any point of the compass. When 1in. spheres are suspended in front of the coil the outer strands of silk assist in determining accuracy of adjustment both vertically and horizontally. The torsion head H, which permits of universal adjustment, is firmly screwed to a beam, B, which is attached to the wall of the room to prevent vibrations of the floor being communicated to the suspended objects.

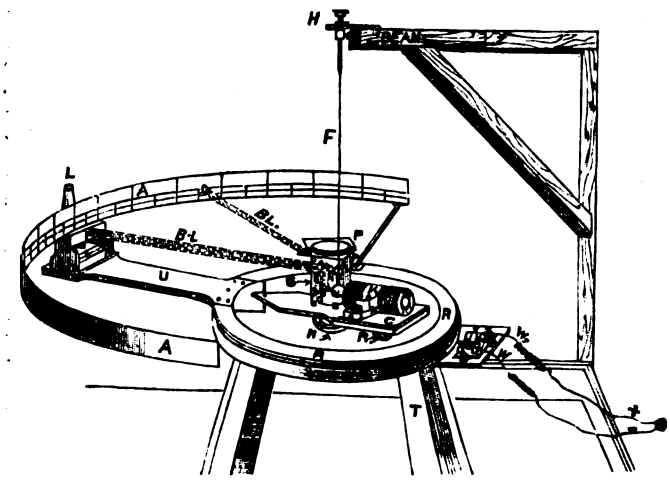

FIG. 1.

A glass cylinder, C, is placed round the suspended bodies to prevent their being affected by currents of air. This is covered with two strips of glass, between which the suspending silk passes down. The spheres, coils, or cylinders S are suspended from the bottom of the mirror rod by means of four loops of narrow silk ribbon, which are bound to the mirror rod with fine silk or cotton. These loops are only large enough to admit the spheres under pressure. The wooden mirror rod is $\frac{1}{8}$th of an inch square, and $2\frac{1}{4}$in. long, a fine copper wire hook being fixed into the upper end for receiving the suspending filament. The glass mirror is circular and fixed into a brass frame. It is capable of being readily adjusted to the mirror rod so as to reflect the light of the lamp. The suspending filaments are made of cocoon silk. Each filament is prepared for use by suspending a weight by it for several days in order to thoroughly strain it and remove twist. The battery power used in these experiments consisted of four, sometimes only three, large Grove cells, the platinums of which were 6in. by 4in.

Contact between the battery and the coil of the magnet is capable of being maintained, notwithstanding the various circular movements of the magnet and carriage, by passing the wires upwards through the table inside the wooden ring R; they are then fixed to the surface of the upper platform by means of two binding screws, from which they are carried in grooves to the bottom of two circular copper troughs to which they are soldered; these troughs surround the axis of rotation. The wires from the coil of the magnet pass downwards, and are soldered to copper rings which fit into and pass nearly to the bottom of the copper troughs. Constant contact is then maintained in any position of the magnet by the mercury with which the troughs are filled. The current is made, reversed, or broken by means of an ordinary commutator conveniently placed. Iron is entirely excluded from the whole of the apparatus upon the table, with the exception, of course, of the core of the magnet.

I believe I have now shown that when a sphere, or other body, is suspended in the glass cylinder in front of the pole of the magnet, (1) it is entirely excluded from external impressions, except such as are made upon it by the action of the electro-magnet through the glass cylinder, but (2) that it is free to move either to the right or left under such influence. I should also state that prior to testing the behaviour of any object under the influence of the magnetic pole, after suspension, it is allowed to come to a state of rest, or as near an approach to rest as can be obtained, as shown by the light on the scale. When this has occurred the zero point of the scale is moved until the light falls upon it; the magnet is then thrown into action by turning on the battery current, and the motions of the suspended objects are carefully noted.

The first object which I tested was made as follows:—A 1in. sphere was turned out of light wood and then flattened at the poles. The plane of the ecliptic was then marked, also the seat of the four magnetic and two geographical poles. Seventy-four pins were driven into the line of the ecliptic, tolerably equi-distant, and one into the seat of each magnetic and geographical pole. One thousand yards of No. ·012 single silk covered and paraffined copper wire having been procured from Elliott Brothers, the covering of the sphere was commenced by placing two strands of wire, each 7in. in length, between every pair of pins in the ecliptic line. The wires were then bent back upon themselves in the shape of the letter V, and each was wound spirally round the hemisphere upon which it was situated, the one having a right, the other a left hand turn, as shown in figure 2, so as to give them a turn and a half round each hemisphere before terminating at one of the magnetic poles, the two ends of each pair on one side of the line being carried to the seat of the two magnetic poles in that hemisphere, the other two ends to the seat of the magnetic poles in the other hemisphere, as nearly as this could be effected with the same inclination, number of strands, and number of turns to each. These windings were so made that the diagonal poles might be brought under the influence of the same wires. The object of the diagonal direction was to cause a more general disturbance of power when the spheroid was subjected to the influence of an electro-magnet.

When all the strands (148) of this layer of wires had been thus laid over the surface of the spheroid they were fixed in their situation by means of india rubber insulite. A second layer, consisting of three strands between each pair of pins, was then laid over the surface in the same manner, and fixed with insulite.

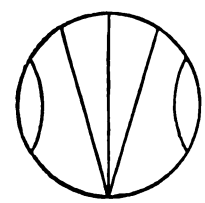

FIG. 2.

Layer after layer was thus superimposed, the number of strands between each pair of pins, as well as the length, increasing with each layer and as the sphere increased in diameter, until the whole of the 1,000 yards had been laid on. The strands of wire were doubled upon each other, and the loop at the end cut off; in this way the proper length of the strands was readily secured, the loss in the length of the wire being considered as under 20 yards. Circular bone pins were inserted in the positions of the terrestrial magnetic poles; a large rod of the same material was passed completely through the sphere; the ends of this last rod were capped with phosphor-bronze points with a view to mounting the globe in conical sockets of the same description. A frame was prepared and the globe mounted so that its axial inclination corresponded with the inclination of the earth.

Previous to mounting, the globe was covered with the same india rubber insulite as had been used in its construction. It was then pressed very accurately into the spherical form, and made to run in the sockets with as little friction as possible. The diameter of the spheroid when finished was 4 inches at the equator and $3\frac{1}{4}$ at the poles.

Experiment 1.—The first attempt to rotate this spheroid was to present it mounted as described to one of the poles of an electro-magnet laid horizontally upon the table, but no motion occurred; the same result followed when a small permanent magnet was approached to another portion of the spheroid.

Digitized by Google

Experiment 2.—The spheroid was now removed from its frame and suspended centrally with the axis of the magnet from a wooden rod by means of several strands of cocoon silk which were attached to the north geographical pole. The surface of the sphere was ¼ of an inch from the pole of the magnet, which was flat at the end. The position taken by the north magnetic poles before battery contact was made was diagonal, as shown in Fig. 3. The circuit

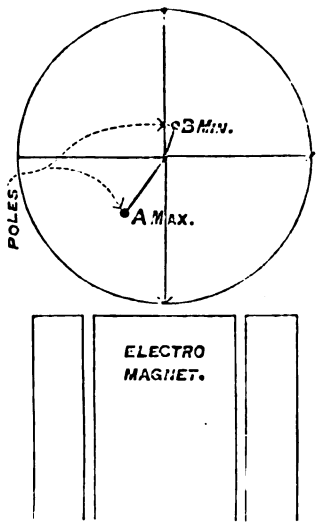

Fig. 3.

was now closed, and almost immediately axial rotation commenced, the maxim pole going from west to east through an angle of more than 90° ; it then oscillated between these two points (see Fig. 4),

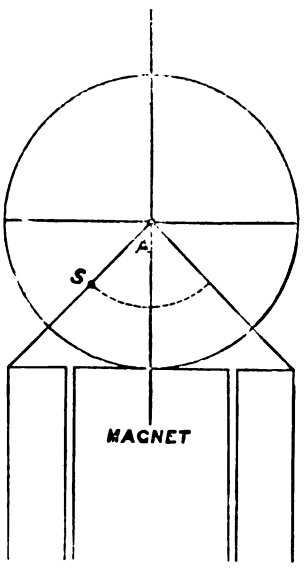

Fig. 4.

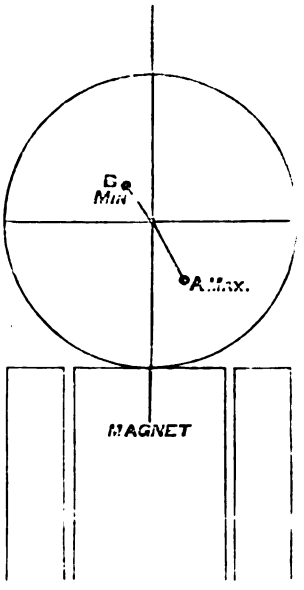

Fig. 5.

but the angle of oscillation decreased, and it finally came to rest about ¼in. to the east of centre of magnetic pole (see Fig. 5). The diameter of the iron core of the magnet was 2in.

(To be continued.)

Frictional Electricity.

5. A pith ball is suspended from a metal stand by a fine thread. If you have a strongly electrified glass rod, how can you find out whether the thread is a conductor or a non-conductor of electricity ?

Answer. On bringing the electrified glass rod near to the suspended pith ball, the pith ball will be attracted, and if the thread be a non-conductor it will, on coming into contact with the rod, receive a charge similar to that of the rod, and will therefore be repelled ; but if the thread be a conductor, the electricity communicated to the pith ball will not be retained by it and therefore the pith ball will remain adhering to the rod.

6. If you were given a negatively electrified stick of sealing wax and two metal balls mounted on insulating supports, how would you, with this apparatus, charge the balls with opposite kinds of electricity ? How could you afterwards find out whether you had charged the balls as you intended, and whether their charges were equal or unequal ?

Answer. Place the two metal balls in contact and bring the electrified sealing wax near to one of them, as shown in Fig. 7, which

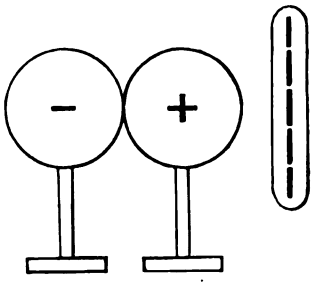

Fig. 7.

will charge them by induction as indicated. Separate the balls by means of the insulating supports before removing the sealing wax, and they will be oppositely charged.

Test them by holding them successively near to the plate of a charged electroscope, and the one whose charge is similar to that of the electroscope will cause a further divergence of the leaves, while the other will diminish their divergence.

To prove that their charges were equal, place them in contact again, and then bring each separately near to the cup of an electroscope, and in neither case will any effect be produced.

7. An insulated conductor, A, is brought near to the cap of a gold leaf electroscope which has been charged positively. State and explain what will happen (1) if A is unelectrified ; (2) if it is charged positively ; (3) if it is charged negatively.

Answer. When A is unelectrified, the leaves will slightly converge, but the effect will be hardly perceptible unless A is large.

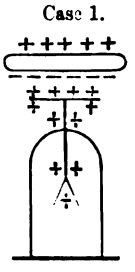

Fig. 8.

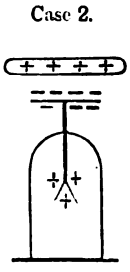

Fig. 9.

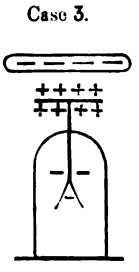

Fig. 10.

The explanation is that A becomes charged by induction, as shown in Fig. 8, and the negative electrification on the side of A near to the electroscope, acting more strongly on the electroscope than the more distant positive electrification, slightly increases the positive electrification of the plate of the electroscope, and therefore diminishes that of the leaves.

When A is electrified positively, it increases the divergence of the leaves, for it diminishes the positive electrification of the electroscope plate, and if brought near enough may even cause an induced negative electrification, as shown in Fig. 9, and therefore at the same time increases the positive electrification of the leaves.

When A is electrified negatively, the leaves will converge when A is brought near to the plate of the electroscope, and as A approaches nearer, they will fall quite together, and then begin to diverge again, for the approach of A to the electroscope increases the positive electrification of the plate, and therefore diminishes that of the leaves, and if brought near enough will ultimately give a negative induced charge to the leaves, as shown in Fig. 10.

8. Describe any experiment by which you could prove that when electrification of one kind is produced the opposite kind is also produced in equal quantity.

Answer. Rub a piece of glass and a piece of resin together, and place both of them in a deep metallic vessel resting on the plate of a charged gold leaf electroscope, as shown in Fig. 11. No effect will be produced on the electroscope, showing that there is no electrification on the outside of the vessel. Then take the pieces of glass or resin and bring them separately near to the plate of the electroscope, when one will cause a divergence and the other a

of the scale can be adjusted to any part of the circumference of the table without disturbing any object which after suspension had come to rest.

Upon the upper platform of the table is a carriage for the magnet G. This is so constructed and placed upon rollers, R, that it is capable of being moved round the suspended objects, the distance from the centre being kept by a central perpendicular pivot or trunnion H, which is embraced by a projection from the carriage just named, and supplemented by another adjustment by means of which the base board of the magnet slides either to or from the centre. By this movement the magnet could be adapted to objects of various sizes.

The coil of the magnet M is placed horizontally in a wooden bracket, or clamp, which also turns upon a central pivot, enabling the axis of magnetic force to be directed to the centre, or to one or the other side of the suspended body. The coil is fixed in position by a brass cap screwed down to the wood on either side.

Accuracy with regard to the axis of magnetic force in relation to the centre of the suspended body is secured by means of six strands of fine silk, which are strained across the aperture of the coil next to the suspended body, one across the centre of the field perpendicular to the axis, and one at a distance of half an inch on either side; these strands are crossed horizontally by three other strands arranged in the same way. A movable brass cap, with central aperture of the same size as the tube in the coil, is crossed by similar strands of silk, and fitted over the other end of the coil. By this arrangement for sighting, coupled with the universal adjustment provided by the torsion head, which will be described, the filament suspending a body in the magnetic-field can be accurately adjusted so as to be in exact line with the axis of the magnet at any point of the compass. When 1in. spheres are suspended in front of the coil the outer strands of silk assist in determining accuracy of adjustment both vertically and horizontally. The torsion head H, which permits of universal adjustment, is firmly screwed to a beam, B, which is attached to the wall of the room to prevent vibrations of the floor being communicated to the suspended objects.

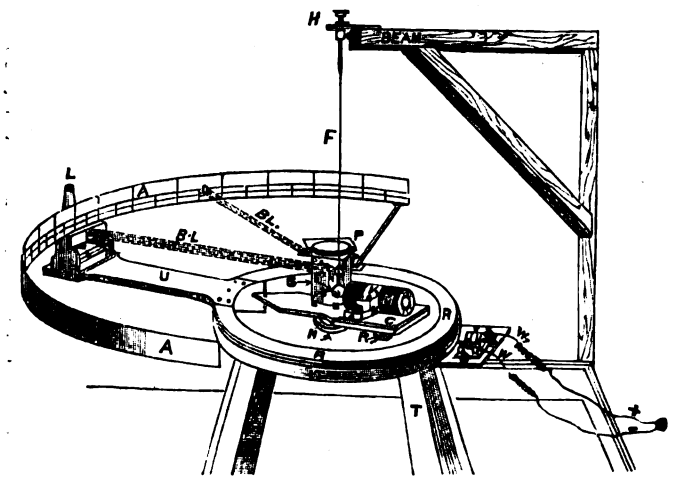

FIG. 1.

A glass cylinder, C, is placed round the suspended bodies to prevent their being affected by currents of air. This is covered with two strips of glass, between which the suspending silk passes down. The spheres, coils, or cylinders S are suspended from the bottom of the mirror rod by means of four loops of narrow silk ribbon, which are bound to the mirror rod with fine silk or cotton. These loops are only large enough to admit the spheres under pressure. The wooden mirror rod is $\frac{1}{8}$th of an inch square, and 2$\frac{1}{4}$in. long, a fine copper wire hook being fixed into the upper end for receiving the suspending filament. The glass mirror is circular and fixed into a brass frame. It is capable of being readily adjusted to the mirror rod so as to reflect the light of the lamp. The suspending filaments are made of cocoon silk. Each filament is prepared for use by suspending a weight by it for several days in order to thoroughly strain it and remove twist. The battery power used in these experiments consisted of four, sometimes only three, large Grove cells, the platinums of which were 6in. by 4in.

Contact between the battery and the coil of the magnet is capable of being maintained, notwithstanding the various circular movements of the magnet and carriage, by passing the wires upwards through the table inside the wooden ring R; they are then fixed to the surface of the upper platform by means of two binding screws, from which they are carried in grooves to the bottom of two circular copper troughs to which they are soldered; these troughs surround the axis of rotation. The wires from the coil of the magnet pass downwards, and are soldered to copper rings which fit into and pass nearly to the bottom of the copper troughs. Constant contact is then maintained in any position of the magnet by the mercury with which the troughs are filled. The current is made, reversed, or broken by means of an ordinary commutator conveniently placed. Iron is entirely excluded from the whole of the apparatus upon the table, with the exception, of course, of the core of the magnet.

I believe I have now shown that when a sphere, or other body, is suspended in the glass cylinder in front of the pole of the magnet, (1) it is entirely excluded from external impressions, except such as are made upon it by the action of the electro-magnet through the glass cylinder, but (2) that it is free to move either to the right or left under such influence. I should also state that prior to testing the behaviour of any object under the influence of the magnetic pole, after suspension, it is allowed to come to a state of rest, or as near an approach to rest as can be obtained, as shown by the light on the scale. When this has occurred the zero point of the scale is moved until the light falls upon it; the magnet is then thrown into action by turning on the battery current, and the motions of the suspended objects are carefully noted.

The first object which I tested was made as follows:—A 1in. sphere was turned out of light wood and then flattened at the poles. The plane of the ecliptic was then marked, also the seat of the four magnetic and two geographical poles. Seventy-four pins were driven into the line of the ecliptic, tolerably equi-distant, and one into the seat of each magnetic and geographical pole. One thousand yards of No. ·012 single silk covered and paraffined copper wire having been procured from Elliott Brothers, the covering of the sphere was commenced by placing two strands of wire, each 7in. in length, between every pair of pins in the ecliptic line. The wires were then bent back upon themselves in the shape of the letter V, and each was wound spirally round the hemisphere upon which it was situated, the one having a right, the other a left hand turn, as shown in figure 2, so as to give them a turn and a half round each hemisphere before terminating at one of the magnetic poles, the two ends of each pair on one side of the line being carried to the seat of the two magnetic poles in that hemisphere, the other two ends to the seat of the magnetic poles in the other hemisphere, as nearly as this could be effected with the same inclination, number of strands, and number of turns to each. These windings were so made that the diagonal poles might be brought under the influence of the same wires. The object of the diagonal direction was to cause a more general disturbance of power when the spheroid was subjected to the influence of an electro-magnet.

When all the strands (148) of this layer of wires had been thus laid over the surface of the spheroid they were fixed in their situation by means of india rubber insulite. A second layer, consisting of three strands between each pair of pins, was then laid over the surface in the same manner, and fixed with insulite.

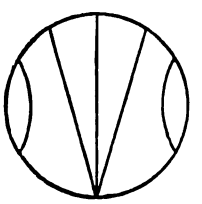

FIG. 2.

Layer after layer was thus superimposed, the number of strands between each pair of pins, as well as the length, increasing with each layer and as the sphere increased in diameter, until the whole of the 1,000 yards had been laid on. The strands of wire were doubled upon each other, and the loop at the end cut off; in this way the proper length of the strands was readily secured, the loss in the length of the wire being considered as under 20 yards. Circular bone pins were inserted in the positions of the terrestrial magnetic poles; a large rod of the same material was passed completely through the sphere; the ends of this last rod were capped with phosphor-bronze points with a view to mounting the globe in conical sockets of the same description. A frame was prepared and the globe mounted so that its axial inclination corresponded with the inclination of the earth.

Previous to mounting, the globe was covered with the same india rubber insulite as had been used in its construction. It was then pressed very accurately into the spherical form, and made to run in the sockets with as little friction as possible. The diameter of the spheroid when finished was 4 inches at the equator and 3$\frac{3}{4}$ at the poles.

Experiment 1.—The first attempt to rotate this spheroid was to present it mounted as described to one of the poles of an electro-magnet laid horizontally upon the table, but no motion occurred; the same result followed when a small permanent magnet was approached to another portion of the spheroid.

Digitized by Google

Experiment 2.—The spheroid was now removed from its frame and suspended centrally with the axis of the magnet from a wooden rod by means of several strands of cocoon silk which were attached to the north geographical pole. The surface of the sphere was $\frac{1}{8}$ of an inch from the polo of the magnet, which was flat at the end. The position taken by the north magnetic poles before battery contact was made was diagonal, as shown in Fig. 3. The circuit

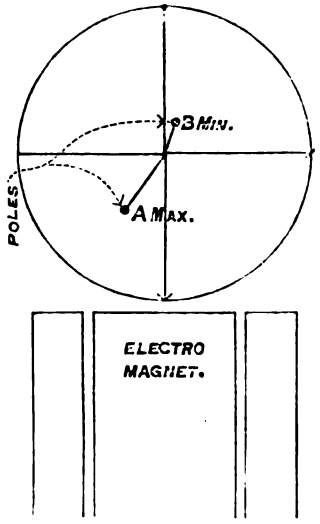

FIG. 3.

was now closed, and almost immediately axial rotation commenced, the maxim pole going from west to east through an angle of more than 90° ; it then oscillated between these two points (see Fig. 4),

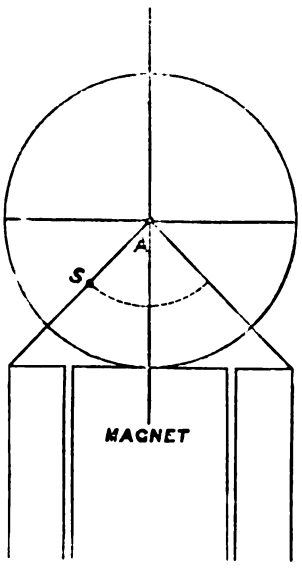

FIG. 4.

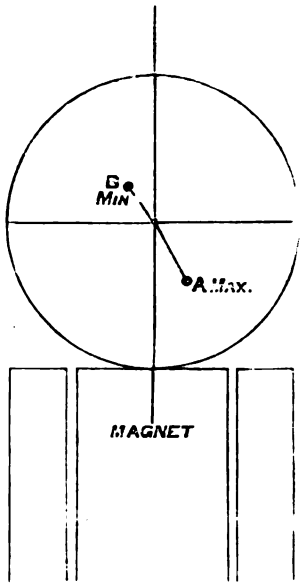

FIG. 5.

but the angle of oscillation decreased, and it finally came to rest about $\frac{1}{4}$in. to the east of centre of magnetic pole (see Fig. 5). The diameter of the iron core of the magnet was 2in.

(To be continued.)

EXAMINATIONS OF THE SCIENCE AND ART DEPARTMENT.

(Continued from page 203.)

FRICTIONAL ELECTRICITY.

5. A pith ball is suspended from a metal stand by a fine thread. If you have a strongly electrified glass rod, how can you find out whether the thread is a conductor or a non-conductor of electricity ?

Answer. On bringing the electrified glass rod near to the suspended pith ball, the pith ball will be attracted, and if the thread be a non-conductor it will, on coming into contact with the rod, receive a charge similar to that of the rod, and will therefore be repelled ; but if the thread be a conductor, the electricity communicated to the pith ball will not be retained by it and therefore the pith ball will remain adhering to the rod.

6. If you were given a negatively electrified stick of sealing wax and two metal balls mounted on insulating supports, how would you, with this apparatus, charge the balls with opposite kinds of electricity ? How could you afterwards find out whether you had charged the balls as you intended, and whether their charges were equal or unequal ?

Answer. Place the two metal balls in contact and bring the electrified sealing wax near to one of them, as shown in Fig. 7, which

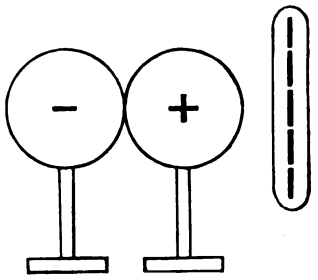

FIG. 7.

will charge them by induction as indicated. Separate the balls by means of the insulating supports before removing the sealing wax, and they will be oppositely charged.

Test them by holding them successively near to the plate of a charged electroscope, and the one whose charge is similar to that of the electroscope will cause a further divergence of the leaves, while the other will diminish their divergence.

To prove that their charges were equal, place them in contact again, and then bring each separately near to the cup of an electroscope, and in neither case will any effect be produced.

7. An insulated conductor, A, is brought near to the cap of a gold leaf electroscope which has been charged positively. State and explain what will happen (1) if A is unelectrified ; (2) if it is charged positively ; (3) if it is charged negatively.

Answer. When A is unelectrified, the leaves will slightly converge, but the effect will be hardly perceptible unless A is large.

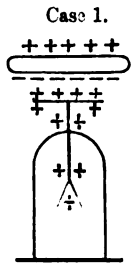

FIG. 8.

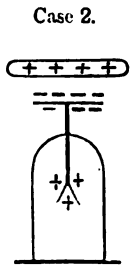

FIG. 9.

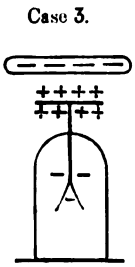

FIG. 10.

The explanation is that A becomes charged by induction, as shown in Fig. 8, and the negative electrification on the side of A near to the electroscope, acting more strongly on the electroscope than the more distant positive electrification, slightly increases the positive electrification of the plate of the electroscope, and therefore diminishes that of the leaves.

When A is electrified positively, it increases the divergence of the leaves, for it diminishes the positive electrification of the electroscope plate, and if brought near enough may even cause an induced negative electrification, as shown in Fig. 9, and therefore at the same time increases the positive electrification of the leaves.

When A is electrified negatively, the leaves will converge when A is brought near to the plate of the electroscope, and as A approaches nearer, they will fall quite together, and then begin to diverge again, for the approach of A to the electroscope increases the positive electrification of the plate, and therefore diminishes that of the leaves, and if brought near enough will ultimately give a negative induced charge to the leaves, as shown in Fig. 10.

8. Describe any experiment by which you could prove that when electrification of one kind is produced the opposite kind is also produced in equal quantity.

Answer. Rub a piece of glass and a piece of resin together, and place both of them in a deep metallic vessel resting on the plate of a charged gold leaf electroscope, as shown in Fig. 11. No effect will be produced on the electroscope, showing that there is no electrification on the outside of the vessel. Then take the pieces of glass or resin and bring them separately near to the plate of the electroscope, when one will cause a divergence and the other a

Digitized by Google

convergence of the leaves. We conclude, therefore, the electrification of the resin is exactly equal and opposite to that of the glass.

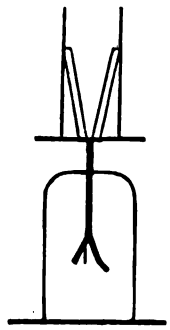

FIG. 11.

9. An orange, into which a sewing needle has been stuck, point outwards, is suspended by a dry silk thread. A charged body is brought near to it, 1st, opposite the point of the needle; 2nd, opposite the side remote from the needle. State and explain the electrical effect in each case.

Answer.—

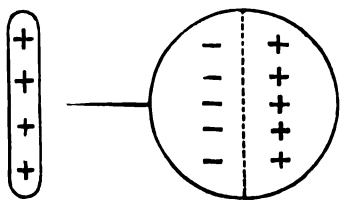

FIG. 12.—Case 1.

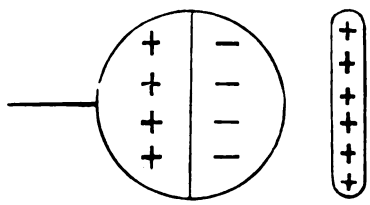

FIG 13.—Case 2.

In each case the orange will become electrified by induction, the nearer side oppositely, and the further side similarly to the electrification of the inducing body. The accumulation of electricity at the point of the needle will cause a high tension, so that in the first case opposite electricity to that of the inducing body will stream off from the point of the needle, leaving the orange charged similarly to the inducing body. In the second case, similar electricity to that of the inducing body will stream off from the point of the needle, leaving the orange charged oppositely to the inducing body.

VOLTAIC ELECTRICITY.

10. Describe and explain any workable experiment to prove that the terminals of a galvanic battery differ electrically in the same way as the conductors and rubber of an electrical machine at work, but to a less extent.

Answer.—The difference between the electrical condition of the terminals of a voltaic battery will not be sufficient to be demonstrated by means of an ordinary gold leaf electroscope, unless a condensing plate be used, as shown in Fig. 14.

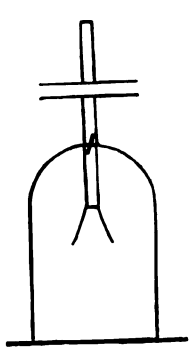

FIG. 14.

Connect the zinc terminal with one of the plates, say, the plate of the electroscope, and connect the copper with the condensing plate, and place the two plates close together without touching, as shown in the diagram, in order to increase the capacity, and therefore give a larger charge to the electroscope. While in this position remove the wires connecting the plates with the terminals of the battery, and take away the condensing plate, when a slight divergence of the leaves will take place.

Now connect the rubber of the machine with one of the plates and the conductor with the other plate, and on turning the machine gently, a much greater effect will be produced at once, without its being necessary, as in the former case, to disconnect, and separate the plates.

It follows, therefore, that the electrical difference is of the same nature in each case, but is much greater in the case of the conductor and rubber of the machine.

11. The platinum and copper plates of a Grove and a Daniell cell are connected by a wire. Would there be a current if the zinc plates were also connected, and if so in which direction would it flow?

What reason have you for your answer?

Answer. Let D (Fig. 15) represent the Daniell, and G the Grove cell.

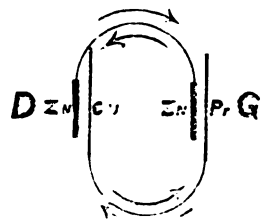

FIG. 15.

The Daniell cell will produce a current flowing in the connecting wires from copper to zinc, as shown by the small inside arrows.

The Grove cell will produce a current flowing in the wires from platinum to zinc, as shown by the larger outside arrows.

The resultant of these two currents flowing in opposite directions will be in the direction of the current due to the Grove cell, and indicated by the large arrows, because the E.M.F. of the Grove cell is greater than that of the Daniell. The strength of the resultant current will clearly be the difference of the strengths of the currents produced by the two cells respectively.

12. The current from a voltaic battery is passed at the same time through a thin wire and through dilute sulphuric acid, connected in series. What will happen to the wire and to the dilute acid; and what change (if any) will be produced in each case by reversing the battery connections, so as to alter the direction of the current through the wire and liquid?

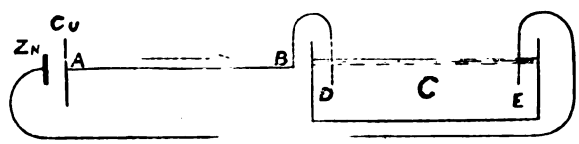

FIG. 16.

Answer. Let A B (Fig 16) be the thin wire, and C the vessel containing dilute sulphuric acid.

In the first case when the current flows from A to B

(1) The wire A B will be heated.

(2) The acid will be decomposed, oxygen being set free at the electrode D, where the current enters the liquid, and hydrogen at the electrode E, where it leaves the liquid.

(3) The acid will be heated by the passage of the current.

On reversing the battery connections so that the current may flow from B to A, hydrogen will be liberated at D, and oxygen at E, but the other effects will continue unchanged.

13. Two compass needles are arranged near each other so that both point along the same straight line. A wire connecting the platinum and zinc ends of a battery is stretched vertically half way between the needles. How will the current in the wire affect the needles, and how will the result depend upon whether the platinum terminal is connected with the upper or lower end of the wire respectively?

Answer. In Fig. 17 B is the battery and A B is the vertical wire, and the figure shows the positions of the needles when no current is passing. If the platinum terminal be connected with the upper end of the wire, and the circuit closed, a current will flow downwards from A to B along the vertical wire, and by Ampère's rule it will be seen that the two poles adjacent to the vertical wire will be deflected westward. If the platinum terminal be connected with the lower end B of the vertical wire the current will flow upwards

Digitized by Google

from B to A, and the poles adjacent to the vertical wire will be deflected eastward.

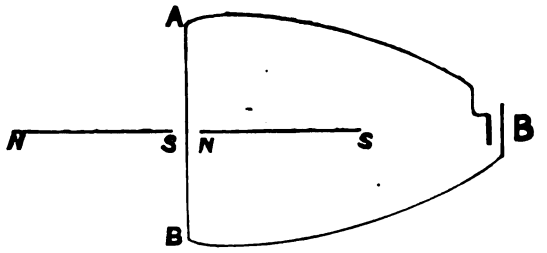

FIG. 17.

14. If you were given any galvanic cell you chose, wire with an insulating covering, and a bar of soft iron, one end of which was marked, state exactly what arrangements you would make in order to magnetise the iron so that the marked end might be a north-seeking pole? Give a diagram.

Answer. Connect the terminals of a battery by means of the insulated wire coiled into a helix, as shown in Fig. 18, and place

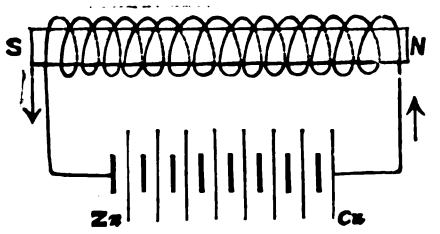

FIG. 18.

the bar of iron in the helix with its marked end at N. Then the current flowing from the copper to the zinc terminal through the helix will magnetise the bar, making the end N in the diagram a north-seeking pole.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis :—

RECHERCHES SUR LA CONDUCTIBILITE GALVANIQUE DES ELECTROLYTES.

BY SVANTÉ ARRHENIUS.

Abstract by OLIVER LODGE. *Remarks by Abstracter in square brackets.*

(*Continued from page 300.*)

§ 10.—Influence of Acid Salts.

Salts called acid are in general completely decomposed by water in sufficient quantity. According to M. Hittorf, acid phosphates are exceptions. Nevertheless, we have proved that NaH_2PO_4 is partly decomposed by great dilution (*see* Part I, § 19).

The ions of acid salts are on the one hand a metal, and on the other the rest of the molecule. If, then, one mixes sulphuric acid with, say, sulphate of soda, a portion of $NaHSO_4$ is formed. But $NaHSO_4$ behaves as any other salt, *i.e.*, its H is not an ion. So that the part of H_2SO_4 contained in $NaHSO_4$ has no effect, *i.e.*, is totally inactive. Thus equilibrating systems are set up which do not agree with calculation based upon the coefficient of activity of H_2SO_4 above given. And an equivalent of acid which forms acid salts (such as sulphuric, oxalic, &c.) cannot completely displace an equivalent of a more feeble acid from its salt, as prop. 33 asserts. [References to Berthelot.]

The calculation of the relative quantities of electrolytes contained in a system where acid salts occur goes on in the manner indicated above. Only it is necessary to observe that if the acid is τ-basic, and if an acid salt is found in which σ hydrogen atoms of the acid are replaced by a metal radical, it loses, for each equivalent of acid salt formed, τ/σ equivalents of acid. So equation (2) becomes—

$$(1-x)\left(n-\frac{\tau x}{\sigma}\right)\alpha\delta=(q+x)(p+x)\beta\gamma,$$

where n is the number of equivalents of acid added since the commencement, and 1, p, q, are the corresponding quantities for base, water, and salt.

If several salts (acid and neutral) form simultaneously, the calculation will be more complicated, as is seen most clearly by an example. Suppose one has at the beginning n. H_2SO_4 and 1. KCl; let there be formed x. K_2SO_4, y. $KHSO_4$, and some HCl; the equation (2A) will take the form—

$$(1-x-y)(n-x-2y)\alpha\delta=(x\beta+y\beta')(x+y)\gamma,$$

where α, β, β', γ, δ are the coefficients of activity of KCl, $\frac{1}{2}K_2SO_4$, $KHSO_4$, HCl, and $\frac{1}{2}H_2SO_4$, respectively.

Between x and y there is a relation which is also a function of the quantities present in the equilibrium of free acids, neutral salt, and solvent, a relation of which the form still remains to be determined by experimental methods.

§ 11. Equilibrium of Heterogeneous Systems.

[By "heterogeneous," Arrhenius means systems out of which one constituent is separated from solution in either the solid or gaseous form, and so removed from action to whatever extent it is insoluble. He quotes from Berthelot and Williamson about the formation of precipitates by double decomposition, and the continual postponement of equilibrium by the dropping out of one constituent.

He then considers a system of four bodies, I_1J_1, I_1J_2, I_2J_1, I_2J_2, of which one (say the last) is but slightly soluble. A constant quantity, c, of this remains in solution, however much of it is formed or destroyed (time being allowed for precipitate to re-dissolve *ad lib.*).

Then, α, β, γ, δ being the respective coefficients of activity, and x the amount of I_1J_2, and of I_2J_1, formed from an original one equivalent of I_1J_1 and any amount of I_2J_2 the equation (2A) is—

$$\alpha(1-x)c\delta=x^2\beta\gamma.$$

x has a magnitude depending on c, and if c happen to be zero, x vanishes.]

We have thus given an analytic proof of the laws of Berthelot.

(37) *If of four bodies,* (1,1), (1,2), (2 1), (2,2), *one of them* (2,2) *has such physical properties that it separates wholly or nearly so from the system, this body* (2,2) *and its conjugate* (1,1) *are formed, to the exclusion more or less entire of the opposite bodies,* (1,2) *and* (2,1).

If *more* than one substance is insoluble the equation may be either

$$x^2\beta\gamma=cc'\alpha\delta, \text{ or } c'x\beta\gamma=c(1-x)\alpha\delta.$$

§ 12. Consequence of the Variation of the Activity Coefficient in Homogeneous Systems.

[Since provisionally Arrhenius supposed the coefficient of activity to be identical with molecular conductivity, he goes on to consider the effect of its varying with pressure and temperature as conductivity does. Pressure variation he considers nil, or unknown. Temperature variation he considers linear, $1+bt$. So he writes (2A)—

$$(1-x)\alpha(1+b_1t)(n-x)\delta(1+b_4t)=x^2\beta(1+b_2t)\gamma(1+b_3t),$$

but then says that the b are about equal for all salts and for all bases, and fairly equal for all monobasic acids; so the temperature terms cancel each other in pairs nearly; and he states the laws.]

(38) *The equilibrium of a homogeneous system is independent of pressure.*

(39) *The relative quantities of four bodies like two acids* and two salts, or two bases and two salts, or four salts, in a system in equilibrium only vary very slightly with temperature.*

The first is in accord with Bunsen and Berthelot: the second with Ostwald, who has verified it between 20° and 100° for HCl, HNO, and two salts of these acids with a single base. He has further shown that these two acids have the same activity between these temperatures by letting them act on calcic oxalate.†

M. Ostwald has also determined the relative coefficients of affinity of different acids with regard to the same base.

He let two acids act simultaneously on a given base—as, for example, KHO, MgO, &c. The acids employed were HCl, HNO, and H_2SO_4. The term "relative coefficient of affinity" expresses the ratio between the fractions of the base which the two acids seize. If one mixes KNO_3 with HCl, one equivalent of each, there will be formed x equivalent of KCl and x of HNO_3, and there will remain $(1-x)$ equivalents of KNO_3 and of HCl. The coefficients of activity being β, γ, α, δ, respectively, x is given by the equation—

$$(1-x)^2\alpha\delta=x^2\beta\gamma,$$

and so the relative coefficient of affinity of HCl : HNO_3 is—

$$Q=\frac{x}{1-x}=\sqrt{\left(\frac{\alpha\delta}{\beta\gamma}\right)}.$$

If instead of potassium one uses sodium, γ and δ remain, but α and β change. Q, however, need not change unless α'/β' is different from α/β. (It acid salts are formed a modification is necessary.)

Molecular conductivities given above (§ 5) make one suspect that changing a base from KHO to ZnO or MgO will diminish the value of Q for $HNO_3 : H_2SO_4$ and for HCl : H_2SO_4.

For the rest, because the activity coefficients of HNO_3 and HCl are about equal, and the same for salts formed from these acids, their relative coefficient of affinity ought to be nearly 1, whatever the base on which they are allowed to act.

Here are Oswald's numbers :—

Table of Relative Affinities.

Base.	$2HNO_3 : H_2SO_4$	$2HCl : H_2SO_4$	$HCl : HNO_3$
OK	2·00	1·94	·97
Na	2·00	1·92	·96
NH_4	1·88	1·81	·96
Mg	1·76	1·74	·99
Zn	1·61	1·53	·95
Cu	1·44	1·40	·97

* Except H_2SO_4 and H_3PO_4.

† Ostwald, *Journal für praktische Chemie* (1877), T. 16, p. 385.

Digitized by Google

In a word, we believe experiment has verified the following rule deduced from the present theory :—

(40) *If an acid HR reacts on a salt MR¹, and if α and β are the activity coefficients of the salts MR¹ and MR, the coefficients of relative affinity between the acids HR and HR¹ vary almost proportionally to the square root of the quotient α/β.*

In the first part, § 13, we remarked that the molecular conductivities of different salts approach each other in such a way that they would seem for extreme attenuation to advance towards a common limit. It follows that the quotient α/β approaches more and more to unity, and that the different values of α/β become equal.

This is why *the relative affinity Q becomes more and more constant as dilution increases*—a relation Ostwald thinks he has already perceived with dilutions less extreme.

The activity coefficients of acids and bases also approach equality as dilution increases.

(41) *Consequently the coefficients of relative affinity of acids approach more and more to unity as dilution increases.*

M. Ostwald has also on this subject made some measurements which confirm the justness of the above proposition. His researches on the magnitude of the co-efficient of relative affinity of H_2SO_4 indicate that at extreme dilutions this coefficient is "almost equal to that of HNO_3, at least it rises to ·9" (that of HNO_3 being 1), while at moderate dilutions it is ·5 or less.

To the invariability of Q for acids and bases M. Ostwald adds a fact of great importance. The molecular conductivities of feeble acids and bases increase very rapidly with dilution, *i.e.*, δ^1 (for weak solution) is much bigger than δ (for strong), so Q increases also if we compare them with strong acids and bases which are nearly unaffected by addition of water, for—

$$Q = \sqrt{\frac{\alpha\,\delta}{\beta\,\gamma}} \text{ for small dilution,}$$

$$Q^1 = \sqrt{\frac{\alpha\,\delta^1}{\beta\,\gamma}} \text{ for large dilution.}$$

Hence—

(42) *The relative affinities of feeble acids and bases (compared with a strong acid or a strong base) increase considerably as dilution goes on increasing.*

This is the reason for not attributing to these "coefficients of relative affinity," or "*avidities*," as M. Thomsen calls them, a too great importance. By believing them constant one seems to have inclined strongly towards regarding them as fundamental numbers. Also the determinations of them by different workers do not agree well with each other.

(43) *As the activity coefficients of different acids change a little unequally with temperature, the relative affinity of two acids ought also to vary with temperature.*

Thus the activity coefficient of H_2SO_4 increases more slowly than that of monobasic acids (HCl or HNO_3), whence it evidently results that its affinity relative to either of these acids diminishes as the temperature rises. We can give only a rough calculation. The temperature coefficient of conductivity for HCl or HNO_3 exceeds by 4 per cent. that of H_2SO_4 at 20° C.; so Q, which is proportional to square root of conductivity, will vary by about 2 per cent. per degree at this temperature.

The temperature coefficient for H_2SO_4 is still less at higher temperature, so its relative affinity ought to diminish faster at these temperatures. Experience agrees with this as well as one can expect.

M. Ostwald has found the following figures for the relative affinity of HCl to H_2SO_4:—

At 0° C. Q = 1·90	At 40° C. Q = 2 02
,, 20° C. Q = 2·00	,, 60° C. Q = 2·37

Between 0° and 40° Q varies about ·15 per cent. per degree, while rough calculation indicated ·2 per cent.; at higher temperatures the variation is greater, as expected. On the other hand, for HCl : HNO_3, Q is almost constant, only varying from 1·00 to 1·02 between 0° and 60°.

A great part of the cited observations (those on H_2SO_4) have been explained by Ostwald as due to the formation of acid salts at moderate dilution. We do not wish to deny this as a *vera causa*. We have already in § 10 shown that the coefficient of activity diminishes for this reason. So naturally Q diminishes too. Nevertheless, it is difficult to explain thus the variation of Q with temperature. It seems much more reasonable to admit the explanation given above.

Finally, we will consider what ought to happen to a salt solution if its temperature rise. For this it is necessary to observe that the temperature coefficient of a concentrated hydrate is much greater than that of a weak solution. Thus, according to M. Kohlrausch*—

For sulphuric acid	at 99·4	per cent.	concentration	b = ·0426
,,	,, 7·73	,,	,,	b = ·0121
For phosphoric acid	,, 87·1	,,	,,	b = ·0374
,,	,, 4·92	,,	,,	b = ·0099
For tartaric acid	,, 49·53	,,	,,	b = ·0263
,,	,, 4·95	,,	,,	b = ·0186
For caustic potash	,, 41·7	,,	,,	b = ·0282
,,	,, 4·19	,,	,,	b = ·0188
For soda	,, 42·72	,,	,,	b = ·0710
,,	,, 2·61	,,	,,	b = ·0195
For ammonia	,, 16·15	,,	,,	b = ·0303
,,	,, 0·1	,,	,,	b = ·0247

As this rule is without known exception, it seems permissible to attribute to water, which is also a hydrate, a coefficient much surpassing the coefficients of dilute compounds (which latter coefficients are almost equal among themseves). Some figures of Ayrton and Perry (*Proc. Phys. Soc.*, II. 178 [1877]) tend to confirm this. Similarly, the coefficient of a salt solution is sensibly greater than that of a hydrate. Looking, then, at the equation of equilibrium of a saline solution—

$$(p+x)\,x\,\alpha\,\delta\,(1+b_1\,t)\,(1+b_4\,t) = (1-x)^2\,\beta\,\gamma\,(1+b_2\,t)\,(1+b_3\,t),$$

we see that b_1 and b_4 are bigger than b_2 and b_3, and therefore that the value of $1-x$ obtained from it will increase with t. But $(1-x)$ signifies the amount of salt decomposed, so—

(44) *The quantity of salt decomposed in a solution is increased if the temperature of the solution rises.*

This will be true also for other electrolytic solvents, according to the law of Hittorf (see § 4). One imagines this important law can be otherwise deduced from a certain dissociation of salt molecules. True, physics show that at high temperatures the movements of molecules are more vigorous. But this does not point out why water then attacks salts more strongly. One often slurs over these difficulties by saying that heating (as well as dilution) brings to the solution a foreign energy opposed to the chemical reactions. But what, then, is the import of chemical laws if they can be annulled by causes which never disappear completely, and of which one does not know how to calculate the effect?

The above law is so generally adopted and verified by a crowd of cases so enormous that it is not necessary to cite any of them.

(To be continued.)

NOTES.

GOOLE.—Tenders are asked for lighting the town of Goole "by gas or otherwise." Information may be obtained from the local authorities.

TECHNICAL EDUCATION.—The Government have definitely abandoned—for the present Session, at all events—their Technical Education Bill.

GLOBULAR LIGHTNING.—During the recent thunderstorms, it is reported that a discharge of globular lightning was observed at Camden Town.

LIVERPOOL.—Messrs. R. W. Preston and Co., a large firm of distillers, have adopted the electric light for their extensive premises at Bankhall. The installation was designed and carried out by Mr. T. M. Bigley, C.E., of Liverpool.

SALE OF ELECTRO-PLATING PLANT.—In our advertising columns particulars will be found of a forthcoming sale of electro-plating and metallurgical plant at Charlotte-street, Blackfriars-road, S.E. The auctioneers are Messrs. Wheatley Kirk, Price and Goulty.

CURIOUS.—By some singular coincidence the greater part of the *Daily News* telegrams "from our own correspondent" which described at length the lighting of the Vienna Opera appeared several weeks previously as an article (presumably an original one) in our esteemed contemporary, *Industries*.

THE PELTIER EFFECT.—At a recent meeting of the Royal Society of Edinburgh Prof. Tait communicated a paper by Mr. Albert Campbell on the direct measurement of the Peltier effect. Mr. Campbell has experimented with three pairs of metals. His results agree in every case with Prof. Tait's thermo-electric diagram.

IMPROVED CARBONS.—It is stated that in the course of some investigations, conducted with a view to obtaining some material which shall be superior to carbon for electric lighting, M. Clingmann has recently experimented with zirconium with considerable success. Pencils of this material will, it is said, last for several months in an arc lamp.

TENDERS WANTED FOR TELEPHONE CABLES.—The *Official Gazette* of Madrid, of the 20th inst., contains an advertisement from the Ministry of the Interior asking for tenders for telephone cables. The amount required is 14,000 metres of fourteen conductors, and 30,000 metres of double conductor. Tenders will be opened on the 19th September.

PRIZE OFFERED FOR A PRIMARY BATTERY.—In connection with the Petroleum Exhibition which is to be held at St. Petersburg in the ensuing winter, the Russian Ministry of War offers a prize of 500 roubles "for a compact and practical galvanic battery for electric lighting with incandescent lamps." A prize of similar amount is offered somewhat indefinitely "for phosphorescent materials and articles."

CITY AND GUILDS OF LONDON TECHNOLOGICAL EXAMINATIONS.—At the late examinations for electric lighting and transmission of power and telegraphy, we observe that the first and the second places in the honours examinations were taken by G. L. F. Phillips and Charles Yeaman respectively, and the second place in telegraphy by Maynard Dodd, all students from Prof. Jamieson's and Mr. Livingstone's classes, at the Glasgow College of Science and Arts. Three others took first class honours.

THE INSTITUTE OF CIVIL ENGINEERS.—The Institute of Civil Engineers has just issued its annual list of the subjects upon which papers are invited. Amongst these the following deal with electrical matters:—"Electro-Motors; their Theory, Construction, Efficiency, and Power." "The Construction and Maintenance of Secondary Batteries." "The Distribution of Electricity for the Lighting of Towns." "The Application of Electricity to the Working of Street Tramways." "The Application of Electricity to Smelting and Metallurgical Operations."

ARC LIGHT PROJECTORS IN THE ROYAL NAVY.—We should like to know whether any good reason can be assigned for the preference shown by the Admiralty for hand regulation of the carbons in projectors. It is difficult to see that any possible advantage is to be gained by giving the blue-jacket who directs the beam a double duty to perform, and the Admiralty must surely be aware that automatic regulation is a very simple affair. In the late naval manœuvres the unsteadiness and coloration of the beams, owing to defective adjustment, was often observable.

"ELECTRICAL PLANT."—We observe with pleasure that Messrs. Wheatley Kirk, Price and Goulty's new trade list meets with continued success, at least so far as the number of advertisements is concerned. As to circulation, a free issue of 1,000 is guaranteed, but the actual number distributed considerably exceeds this figure. We would venture to make one small suggestion calculated to increase the usefulness of the publication, namely, that plant of all descriptions which is available for hire as well as purchase should be indicated throughout by an asterisk.

MOTORS IN THE STATES.—According to the New York *Electrical World* the number of electric motors now running in the States may be taken at about 10,000. We doubt whether in this country the number in actual use exceeds 400 or 500. In America one company alone has sold over 2,000 motors, while another has built 2,500 *since last November*. It was at first supposed that the demand would be chiefly for machines of 5 horse-power and under, but it is found that the demand is brisk up to 10 and 15 horse-power. The larger sizes are chiefly used for printing machinery.

TRANSMISSION OF ENERGY IN NEW ZEALAND.—In a handbook recently issued by the New Zealand Government and devoted to a description of the mineral resources of that country, there is a detailed description of the electrical transmission of energy which is employed for working the stampers at the Phœnix Gold Mines, Upper Shotora, Otago. Power is derived from a waterfall at a distance of 2½ miles. We gave a full description of this installation some twelve months ago, and are glad to hear of its continued successful working. It may be remembered that the plant was supplied by the Anglo-American Brush Co., and consists of a pair of Victoria dynamos.

MR. ELLIS LEVER'S PREMIUMS.—In addition to the renewed offer of £500 for an electric safety lamp, Mr. Ellis Lever has decided to repeat his offer of £500 for a perfectly safe, practical, and efficient means of blasting without gunpowder. He has communicated his intention to the Home Secretary; and on the condition that the Government will undertake the necessary tests and make the awards, he has offered to place in Mr. Matthews' hands £1,000, to be awarded in two premiums of £500 each—one for the best method of safe blasting in coal mines without the use of gunpowder, and the other for a safe system of electric lighting in mines to supersede the present so-called safety lamp.

WHITWORTH SCHOLARSHIPS FOR 1887.—The results of the examinations for Sir Joseph Whitworth's Scholarships in Mechanical Engineering Science have just been sent to the successful candidates, and we have again to intimate the more than usual success of Glasgow students. This year 25 scholar-

Digitized by Google

ships have been awarded, one of £200, eight of £150, and sixteen of £100. On the whole, with the exception of Glasgow, these scholarships are pretty well distributed throughout the United Kingdom. The first scholarship of £200 has been awarded to a Mr. Whitaker, of Burnley. Six scholarships have been taken by Glasgow men, and of these the first five, of a value of £150 each, fall to students trained at the Glasgow College of Science and Arts, making a total of 17 Whitworths taken by this Institution in four years (£2,300).

M. Menges' Electrical Governor.—In another column will be found a letter from M. Menges, in which he takes some exception to a note in our last issue, refering to his electrical governor. We had before us at the time a very enthusiatically-written article in one of our French contemporaries, in which the elementary notion of an electrical governor was spoken of as something entirely new and worthy of the highest admiration. The details were not very clearly given, but so far as they could be gathered the description certainly justified us in speaking of the idea as being put into operation "in a somewhat crude form." However, we shall hope very shortly to place our readers in a position to judge for themselves as to the merit of the device, of which now that we have a description at first hand it is possible to speak in very different terms.

University College, Dundee.—We have received a copy of the calendar for the fifth session of the University College, Dundee, and are pleased to note the continued success and enlarged scope of the operations of this institution. The college was founded in 1880, chiefly by the munificence of Miss Baxter, of Balgarris, who at different times has contributed to the foundation and endowment funds no less than £140,000. By the deeds, the trustees are directed to apply the means put in their hands "to founding, establishing, endowing, maintaining, and conducting a college for promoting the education of persons of both sexes, and the study of Science, Literature, and the Fine Arts." As regards the subjects in which we are most interested, the names of the professors who occupy the principal chairs are a sufficient index of the rank which the Dundee College occupies in the teaching of science. The chair of Engineering is filled by Prof. J. A. Ewing, F.R.S.; Chemistry is taken by Prof. J. Carnelley; and Mathematics and Natural Philosophy by Prof. J. E. A. Steggall.

The Telegraph in Japan.—The progress of telegraphic enterprise in Japan and the neighbouring countries is strikingly shown by the figures quoted in Consul Sir F. R. Plunkett's report from Nagasaki. The inland (Japanese) messages passing through Nagasaki last year numbered 201,979, against 142,250 in the preceding year. The foreign messages (outward) were 17,501, against 15,134 in 1885; inward 17,322, against 15,874 in 1885. The great increase in the number of international messages in the last eight years —in 1878 the total was under 3,600—is due to the development of the Chinese telegraph system, especially in those ports which have steam communication with Nagasaki, and to its extension from the Chinese frontier to Chemulpo and Söul in Corea. A still further increase may be looked for on the completion of the land line connecting Söul with Fusan, and telegrams will then be transmitted by the Nagasaki and Fusan cable instead of passing over the Chinese system. This line is expected to be in working order before the end of the present year.

Tests of Electrical Instruments at the Antwerp Exhibition.—The publication of the result of the tests of electrical instruments and apparatus made at the Antwerp Exhibition of 1885 has been long delayed, but we learn that it will now make its appearance very shortly. According to our contemporary, *l'Electricien*, the result of the examination of two types of industrial ammeters and voltmeters in most frequent use has not been very satisfactory. In some cases the error has exceeded 7 per cent.; this is the more unsatisfactory as it may be supposed that the instruments sent for trial were calibrated with special care, and are scarcely likely to have received much rough usage. Our contemporary refers also to the Ferranti coulomb-meter, the constant of which instrument (the figure representing the number of turns per hour corresponding to one ampere) was found to increase with the current. For instance, at 7 amperes the constant was 608, at 14·7 amperes 662, and at 22·7 amperes 697. We believe, however, that Mr. Ferranti has succeeded in remedying this serious defect in later types of his instrument.

Some Belgian Tenders.—Tenders were recently asked for an installation of 400 16 candle-power lamps in a new military hospital in this city. Two engines, each of twenty-five indicated horse-power, with separate boilers and accessories, were to be provided. The Société Phœnix-Edison, of Ghent, tendered for 69,000 francs, and the Société Electricité et Hydraulique, of Charleroi, tendered for 67,000 francs.—For the lighting of the Schaerbeek Railway Station, for which no exact specification was issued, the following tenders were received:—(1) M. Schuckert, twenty-four arcs of 600 candle-power, at the rate of 0·52 franc per lamp-hour for the first 3,000 hours guaranteed, 0·45 franc for the next 500 hours, and 0 40 franc for the remainder. Estimated cost of plant 114,512 francs, of which the State should pay 38,000 francs on terminating the contract. (2) La Société d'Eclairage du Centre; (*a*) 11 arcs of 1,100 candles (mean spherical intensity) at the rate of 0·67 franc for the first 3,000 hours guaranteed, 0·55 franc for the next 500 hours, 0·45 franc for the remainder. Estimated cost, 57,500 francs, of which the State should pay 18,500 at the end of the tenth year. (*b*) Sixteen arcs of 900 candle-power at the rate of 0·54 franc for the first 3,000 hours guaranteed, 0·45 franc for the next 500 hours, and 0·35 franc for the remainder. Estimated cost, 65,500 francs; 24,500 francs to become payable at the end of the tenth year.

Long Distance Telephony in the States.—The telephone line between New York and Philadelphia, which was opened for the public service in January last, has proved quite successful in operation, although a good deal more work could be got out of it than is yet required. It may perhaps be remembered that the line consists of no less than fifty wires—twenty-five circuits—of hard drawn copper wire. At present the communications amount to between 150 and 250 a day, while a steady increase is perceptible. The tariff is $1 for five minutes, no charge being made if the person inquired for is not found. In New York there are 130 private firms in direct communication with the Philadelphia line independently of the local exchange, and in Philadelphia there are 40 similar connections. The number is smaller at Philadelphia, because the company has put up instruments at the chief hotels for public use. In starting with as many as twenty-five circuits the idea entertained was that many of them could be leased outright to private firms or corporations. This has been done to a certain extent, and other wires are jointly rented by a number of firms. Several smaller towns upon the road have recently been placed upon the circuit. The success of the company has been sufficiently marked to induce them to extend their operations. Thirteen circuits are already at work to New Haven, and lines are in progress from New York to Boston, Albany, Washington, and several smaller towns.

MUTUAL INDUCTION COEFFICIENTS.—It is well known that when two coils wound upon the same iron core with coefficients of self-induction L_1 and L_2, the maximum possible value of their coefficient of mutual induction is equal to $\sqrt{L_1 L_2}$. This value of M is obtained on the assumption that each coil is traversed by the whole of the lines belonging to the other coil, a condition which is most nearly fulfilled when the two coils are wound upon a closed iron core, especially if the whole of the surface is covered by each coil. The *Electrotechnische Zeitschrift* has recently published the result of some experiments on various coils with a view of determining the difference between the observed and calculated maximum of M. This table we reproduce below, and it will be observed that the difference is very small. It is, however, obvious that the experiments are not of much practical value unless accompanied by information as to the size, shape, and structure of the coils. The question is, in fact, merely one of magnetic leakage.

	Resistance.		Number of Turns.		L_1.	L_2.	M.	$\sqrt{L_1 L_2}$.
	Primary.	Secondary.	Primary.	Secondary.				
1	0·4	234	160	7980	0·0012	0 60	0·026	0·0268
2	2 2	680	435	4400	0·0073	0·71	0·067	0·072
3	281	281	...	...	0·22	0·22	0·219	0·22

PROPOSED ELECTRIC TRAMWAY FOR LEEDS.—On Tuesday the Leeds Town Council discussed several projects for constructing a railway or tramway from the heart of Leeds to Roundhay Park, with the view of making that pleasure resort more available to the public. Mr. Lupton informed the Council that at his request Mr. M. Holroyd Smith, electrical engineer, of Halifax, was present, and, if allowed, would explain his scheme for the construction of an electrical railway.—Mr. Smith said that it was quite within his experience to be able to make a line from the centre of the town to Roundhay Park, and back again, to work it by electricity, with more safety and more regularity, and at a lower rate than it could be worked by any other means. It was the best power for meeting an exceptional increase in the quantity of traffic. On the line at Blackpool the number of passengers carried during six days in the winter was 2,393, and the cost for fuel and wages was under £24; but in September, 1886, during the height of the season, the number of persons carried over a distance of two miles in the same period was 44,306, while the cost for wages and fuel was only increased to £45. He was quite prepared, whether a tramway line was made a subway line or an overhead line, to be at the cost of all the electrical working of that line, and would guarantee that he did it at a less cost per mile than could be undertaken by any other system. In answer to questions, Mr. Smith said that he had undertaken to work cars up a gradient of 1 in 8, and that there would be less difficulty in working a railway than a tramway. The Council took no definite action at the meeting, but an opinion was strongly expressed in favour of some scheme which would not require the use of the public roads.

THE THUNDERSTORMS.—At the close of last week further thunderstorms were reported from various parts of the country. At Rawmarsh, near Rotherham, a collier named Charles Thompson was killed by lightning. He and another collier named George Grey left the pit to return home, and, being overtaken by the storm, sought shelter under an oak tree in the middle of a lane. A flash of lightning struck the tree, passed down its trunk, and struck the two men beneath it. Thompson was killed on the spot, having been struck on the head, and his clothes were torn and the buttons melted off. Grey was badly injured, and is not likely to recover. A West Riding policeman was taking shelter from the rain against a wall in the yard, when he was struck and rendered insensible. Much damage was done in Brimington, a village about two miles from Chesterfield. Four houses were struck, and one suffered terribly. The lightning, it appears, attacked the end of the building, passed on to the front of the house and entered the sitting room, carrying with it the window frame and glass and smashing to atoms all the furniture. The roof was left without a single slate, only about a couple of copings remaining, and these were midway between the roof and square of the building. The windows throughout the whole house were blown out, the sash weights and fire grate being piled up in a corner of the top front bed room, and the cupboards presented the appearance of a pottery scrap heap. The roof of an adjoining house was partly taken away. The clock chain was melted as if it had been in a furnace. The other houses were more or less seriously damaged, the walls being dislodged several inches. No lives, however, were lost.—An inquest was held at Birmingham recently on the bodies of the two men, Lockyer and Stainer, who were killed by lightning at the Atlas Brickworks during the storm of Wednesday week. The men had taken shelter in a hut when the chimney stack, 140ft. high, was struck by lightning; the discharge passed through the hut and killed the two men. There was a mark of scorching on the back of Lockyer's right leg, the hair on the right side of both was singed, and there was a mark like an impression of a tree on the chest of each man. A verdict in accordance with the evidence was given, and it was recommended that a lightning conductor should be attached to the stack. Some curious and terrible effects of lightning are reported from Mende. During the recent thunderstorms in that locality the room of a Madame Gaillard was suddenly illuminated with the flashes of fire. The woman and her three children, frightened out of their wits, ran for safety to the chimney corner, when a single sharp clap of thunder was heard over the house, and the chimney was struck by lightning. The mother and the three children were knocked down insensible. One of them, a boy of four, was killed instantaneously; and a little girl was whirled into the centre of the room, and had her eyes completely burned out.

THE BRITISH ASSOCIATION MEETING.—The following is the programme of the forthcoming meeting of the British Association at Manchester, over which Sir Henry Roscoe will preside:—Wednesday, August 31st: President's address, in the Free Trade Hall, at 8 p.m. Thursday, September 1st: Sectional meetings, 11 a.m. to 3 p.m.; *Conversazione* at the Royal Jubilee Exhibition. Friday, September 2nd: Sectional meetings, 11 a.m. to 3 p.m.; Lecture by Prof. H. B. Dixon, M.A., F.R.S., on "The Rate of Explosions in Gases," in the Free Trade Hall, at 8:30 p.m. Saturday, September 3rd: Sectional meetings, 11 a.m. to 1 p.m.; Excursions; Lecture to working men, by Prof. George Forbes, F.R.S., on "Electric Lighting," in the Free Trade Hall, at 8 p.m. Monday, September 5th: Sectional meetings, 11 a.m. to 3 p.m.; Lecture by Colonel Sir Francis de Winton, K.C.M.G., R.A., F.R.G.S., on "Explorations in Central Africa," in the Free Trade Hall, at 8:30 p.m. Tuesday, September 6th: Sectional meetings, 11 a.m. to 3 p.m.; *Conversazione* at the Town Hall. Wednesday, September 7th: General meeting in the Chemistry Lecture Theatre of Owens College, at 2:30 p.m. Thursday, September 8th: Excursions. In Section A (Mathematics and Physics) the presidential chair will be occupied by Sir Robert S. Ball, the Astronomer Royal of Dublin, who is expected to discourse on "The Theory of Screws." Sir Robert has the

Digitized by Google

reputation of a wit, and his address is looked forward to with considerable interest. We have, indeed, heard it rumoured that the subject will be treated in its broadest aspect (including the human species), and that there will afterwards be a practical demonstration of the theory of cork screws. Some of the most serious and important work of this section will be done in connection with the theory of electrolysis, to the report on which subject our readers are aware Prof. Oliver Lodge has devoted himself with unremitting energy during the last twelve months. The discussion will probably be held on Saturday, and on this occasion the chemical and physical sections will unite. It is also anticipated that some important experimental results in electrolysis will come from Owens College. If time permit it is intended to have a discussion on the report of the committee on the vexed question of electrical standards. Mr. Preece will read a paper on the specific resistance of commercial iron wire, and another on the coefficient of self-induction of telegraph wires, and on the induction between wires and wires. The result of the new magnetic survey undertaken by Profs. Thorpe and Rücker will be communicated, and Mr. Haldane Gee will exhibit a comparison magnetometer. In the section of Mechanical Science, where Prof. Osborne Reynolds occupies the chair, Mr. Gisbert Kapp will read an interesting and important paper "On the Condition of Maximum Output by Alternating Current Dynamos." The paper will also contain the results of an investigation of the conditions for obtaining maximum work from a series-wound motor supplied with an alternating current.

THE LIGHTING OF THE VIENNA OPERA.—The electric lighting of the Vienna Opera, which has recently created so much attention on the part of the non-technical press, is really a noteworthy affair, inasmuch as it constitutes beyond all comparison the most extensive, and in some respects the most severe, test to which secondary batteries of recent design have as yet been put. The cells, 1,296 in number, were supplied by the Electrical Power Storage Company. They each contain 31 plates, and the total weight of plates alone is approximately 100 tons. The boxes, which are of glass, are erected on stands, six tiers high, each cell resting on a separate tray supported by oil insulators. The accumulator is subdivided into twelve batteries, each consisting of 54 elements of 2 cells in parallel; during charge the accumulator is arranged in 4 series sets of 3 of the batteries coupled in parallel, thus practically forming the total of 218 elements of 6 cells in parallel, and requiring a charging electromotive force of 540 volts at the battery terminals and a current of 360 amperes. The discharging capacity is 144,000 watts, or, in other words, 2,440 sixty-watt 100-volt lamps can be supplied without the aid of the machinery for nine hours. The cells have been put together and erected by the Electrical Power Storage Company's staff at Vienna, the contract for accumulators having been received direct by that company from the Imperial Continental Gas Association. The whole of the remaining work, including the supply and erection of engines and dynamos, was entrusted by the Imperial Continental Gas Association to Messrs. Crompton and Co., who have supplied five of their own machines, coupled direct to Willans engines. The engine plant is placed in a large building, formerly occupied by the British Embassy, at a considerable distance from the theatre. Each dynamo is wound for a current of 120 amperes at 600 volts, the armatures being 36in. in length, the fields are separately excited, and the engines are supplied with Willans electric governors, the regulation being for constant current. The engines are single acting compound, of the well-known Willans high-speed type, in which the cut-off is effected by an excentric upon the crank pin. The boilers were supplied by an Austrian firm to Messrs. Crompton's specification, and are capable of developing 800 horse-power, reckoning 30lb. of water per indicated horse-power. Water is obtained from a well sunk on the premises, and is passed through Clark's combined feed-water heaters and filters, being finally forced into the boilers by a pair of Worthington high-pressure pumps. Provision is made for the ultimate increase of the whole of the plant to double its present capacity, inasmuch as the station is intended for the supply of other installations besides the one already at work. The mains are laid underground, and consist of lead-covered cables of the Berthoud-Borel type. We have previously given some account of the interior fittings at the Opera House, which are of a very substantial and elaborate description.

ELECTRO-MOTOR TARIFFS IN AMERICA.—There is at present great discrepancy in various cities in the States, both as to the method and the rate at which electric energy is supplied. The following tariffs, collected by the New York *Electrical World*, will, however, prove interesting. At Pittsburgh:

Where Company Owns Motor. Size.	Per month.	Where Subscriber Owns Motor. Size.	Per month.
½ horse-power	$10.00	½ horse-power	$6.00
1 ,,	15.00	1 ,,	10.00
1½ ,,	22.50	1½ ,,	15.00
2 ,,	28.00	2 ,,	20.00
3 ,,	40.00	3 ,,	25.00
5 ,,	60.00	5 ,,	40.00
8 ,,	72.00	8 ,,	55.00
10 ,,	80.00	10 ,,	60.00

The company runs its main line to the premises where the motor is to be placed, but all other connections and appliances for the purpose of utilising the power from that point are made at the cost of the subscriber.

At Buffalo, N.Y.:

Size.	Power per month.	Rental of Motor per month.
⅛ horse-power	$3.00	$0.50
¼ ,,	5.00	1.00
1 ,,	8.00	1.00
2 ,,	15.00	2.50
4 ,,	26.00	5.00
6 ,,	38.50	7.50
8 ,,	51.00	10.00
10 ,,	63·50	12.50
12 ,,	76.00	15.00

The above quotations are based on a service daily, except Sunday, from 7 a.m. to 6 p.m. Special prices are made where power is required for a different period. A discount of $1 per motor is made on bills paid on or before the 10th of month following service. Where motor is furnished by the company, a contract for at least one year's motor use is required.

At Laramie, Wyo.:

Horse-power delivered to customers.	Rates per horse-power per hour.	Rate for one hour.	Rate per month of 26 days in cases where consumer owns the motor.
40	2½ cents	$1.00	$260.00
20	2½ ,,	0.50	130.00
15	2½ ,,	0.37½	97.50
10	3 ,,	0.30	78.00
7½	3½ ,,	0.26¼	68.25
5	4 ,,	0.20	52.00
3	4½ ,,	0.13½	35.10
2	5 ,,	0.10	26.00
1	—	0.06	15.00
½	—	0.03	7.50
For sewing machines.	—	—	2.00

The Laramie station is about to supply 40 horse-power at $260 per month, as above, to a large flour mill about 150 feet away. The following are other rates quoted:—Detroit, $100 per horse-power per annum; Boston, 50c. per horse-power per day; Des Moines and four small towns, $100 per horse-power per annum at ten hours daily, constant load. New York averages $100 to $125 per horse-power per annum; Lawrence, Lowell, Harrisburg and Providence, $125 per horse-power per annum; Cleveland, Cincinnati and Baltimore, $10 per horse-power per month; Rochester (power derived from turbines at generating station), $50 to $72 per horse-power per annum. At Cleveland,

Digitized by Google

twenty-four sewing machines rated at $\frac{1}{8}$ horse-power are run at $1 each per month. In all cases lower rates are charged for larger powers.

"THE ELECTRICITY OF CONTACT OF GASES WITH LIQUIDS."—Under this title there is an important letter from Mr. Enright in last week's *Nature*. "Since the delivery of Helmholtz's famous Faraday lecture 'the charge on the atom' has been assumed by physicists, notwithstanding the very serious objections urged by Maxwell against such a theory. A reperusal of the letter, some eighteen months ago, excited me to make some experiments on the subject." Experiments led at first to results of a very baffling and apparently contradictory character. A quadrant electrometer was connected on one side to earth and upon the other to an insulated stand on which was placed a porcelain dish, containing a small quantity of distilled water. Small pieces of potassium or sodium were thrown on the water, and the nature and amount of the charge left on the vessel was noted. This charge was of course opposite and equal to that obtained by the escaping hydrogen. With water the observations were inconstant and conflicting, but ultimately two definite and constant results were obtained: "(1) Na thrown on strong and pure acetic acid invariably left a positive charge on the insulated dial, the escaping hydrogen being negative; (2) a fragment of zinc thrown into strong HCl invariably left a negative charge on the insulated dial, the escaping hydrogen being negative." The next experiment tends largely to clear up the whole question. We omit the precautions observed and give the result:—"The porcelain dish was nearly filled with a 10 per cent. solution in distilled water of strong HCl. Three small fragments of granulated zinc were now dropped into the dilute HCl in the insulated dish. A very slight effervescence at once appeared. This gradually increased, but never became violent. In four minutes from dropping the zinc the spot could be perceived moving, and in four and a-half minutes more it moved twenty-eight divisions to the left, indicating the charge on the dish negative and the escaping hydrogen positive. The insulated stand, &c., was now disconnected from the quadrants. The spot maintained its position on the scale. In one and a-half minute after the quadrants were again connected to the insulated stand. The spot moved instantly twenty divisions more to the left. In one and a-half minute more it had moved ten divisions further to the left, but with a slower pace, and it presently stopped and turned back, at first slowly, taking five minutes to go back the sixty-eight divisions to the zero. In four minutes more it had moved eighty divisions to the right. The insulated stand was once more disconnected from the quadrants, and at the end of two minutes they were reconnected, when the spot instantly bounded up 55 divisions further to the right. It continued to move in the same direction until the effervescence ceased owing to the acid being exhausted. A quantity of the zinc survived. On short-circuiting the quadrants the spot returned to within four divisions of the original zero. As the reaction between zinc and hydrochloric acid proceeds, the quantity of chloride of zinc in solution continually increases, and so it appears demonstrated that when hydrogen passes through hydrochloric acid it acquires a positive charge, when it passes through chloride of zinc it acquires a negative charge. I believe that this inference may be safely very much generalised, but for the present I forbear. In confirmation of it, however, it may be well to mention that at any stage of the last experiment a deflection may be obtained to right or left as required by adding an excess of saturated chloride of zinc (for the first), or of hydrochloric acid (for the second). When it is known that the sign of the charge on escaping hydrogen depends upon the substance it has been in contact with, the very irregular results with K and Na already mentioned become less mysterious."

TRANSMISSION OF ENERGY.—COMPRESSED AIR v. ELECTRICITY.—*The Times* of August 24th contained an elaborate eulogy of the system of transmitting energy by means of compressed air, and, indeed, if commercial considerations be neglected, we should be disposed to agree with most, if not all, the writer says. That still more sapient oracle, the *Pall Mall Gazette*, evidently supposes that compressed air is a brand new invention, and, after reading the account, thus learnedly comments thereon:—"It is a good instance of the busy march of science in these days that while electricity is only on the threshold of its applications, a rival power should already be in the field, the substitution of air for steam! It would require volumes to expound all that would be meant by such a change," &c. Without employing "volumes" of vapour upon the subject, we would invite the attention of the *Pall Mall Gazette*, as representing the average non-technical mind, to the following facts and figures, premising only that *cost* is usually an essential consideration in matters of this kind. It has recently been shown by a writer in the French journal, *La Genié Civil*, that the efficiency of transmission by compressed air cannot exceed 45 per cent. for distances of about a quarter of a mile, while beyond this it is still less, and that the system is necessarily dearer than transmission by water pressure, except for distances exceeding about three miles. The calculation is based upon a total transmission of 100 horse-power. Now (quoting from the same writer) let us compare each of these methods with the cost of transmission by electricity and with wire ropes. The result is shown in the following table, where the original source of power is (1) steam, (2) turbines:—

System employed.	330 Feet.	1,640 Feet.	3,280 Feet.	16,400 Feet.	32,810 Feet.	65,620 Feet.	Motor.
	d.	*d.*	*d.*	*d*	*d.*	*d.*	
Electricity ...	1·80	1·84	1·94	2·27	2·84	4·61	Steam.
Water pressure	2·27	2·36	2·61	4·03	5·79	9·57	
Compressed air	3·17	3·23	3·33	4·05	5·25	6·39	
Ropes	1·26	1·49	1·58	2·88	4·99	12·68	
Electricity ...	0·40	0·48	0·53	0·62	0·68	1·15	Hydraulic.
Water pressure	0·47	0·55	0·62	1·33	2·23	3·54	
Compressed air	0·77	0·80	0·84	1·21	1·86	3·36	
Ropes	0·26	0·27	0·30	0·80	1·42	3·39	

It will be seen that for 100 horse-power compressed air is absolutely the most expensive method in all cases. For distances less than 16,400ft. wire ropes are at first cheaper, while beyond such distance electricity comes rapidly and unmistakably to the front. But immediately we contemplate not merely the transmission but also the *distribution* of energy, ropes are altogether out of the question, and cannot for a moment compete with electricity for convenience and ease of handling. Relative calculations of this general nature do not, of course, pretend to anything more than an approximate degree of accuracy; but it may be stated that similar calculations by independent authorities have invariably given results of the same general character. (See, for instance, the valuable tables in Kapp's "Electrical Transmission of Energy.") The proof of the pudding is, after all, in the eating, and it may astonish *The Times* and the *Pall Mall* to learn that in America there are already in active operation about 10,000 electro-motors, of which the great majority receive current from central stations for the distribution of light and power. Such stations number about 250, scattered in almost as many different towns.

COMPARISON BETWEEN THE VIEWS OF DR. ARRHENIUS AND PROF. ARMSTRONG ON ELECTROLYSIS.

REPLY TO PROF. LODGE'S CRITICISMS.

BY HENRY E. ARMSTRONG, F.R.S.

A Communication to be made to the Electrolysis Committee of the British Association.

Prof. Lodge in his summary very clearly points out the difference in the views advocated by Arrhenius and myself, and emphasises the chief points which it is of importance to discuss. He unreservedly condemns my hypothesis, on the ground that any E.M.F., however small, is sufficient to produce sensible electrolysis; and he asserts this to be a proof of the correctness of the orthodox view that the E.M.F. has nothing to do but to give direction to the already separated atoms. I have before expressed my doubt of the force of this argument; but I may add that it appears to me hopeless to attempt the experimental disproof of such a statement, our ability to prepare pure substances being out of all proportion small as compared with our power of detecting electric currents: indeed, it would be presumption to attempt to contend with an engine of such surpassing delicacy as "a galvanometer sensitive enough to show a current which could only decompose a milligram of water in a century."

It is apparently desirable that I should more fully state, from a chemist's point of view, the chief reasons which cause me to hesitate in accepting the "atomic dissociation hypothesis," and which have led me to suggest an alternative "molecular hypothesis," viz., that in the case of "composite electrolytes," at all events, electrolysis is the outcome of the combined action of the E.M.F. and of some effect which the one set of molecules exerts upon the other set while both are under the influence of the E.M.F. I care little at present what the effect is, the important question to settle being whether electrolysis is primarily an affair of atoms or of molecules.

1. In explanation of the fact that neither hydrogen chloride (HCl) nor water (H_2O) is an electrolyte, although a solution of the one in the other conducts readily, it has been sometimes assumed that the dissociated atoms of H and Cl are shielded and prevented from recombining by the intervention of the neutral molecules of the solvent, opportunity being thus given for the E.M.F. to act and give direction to the atoms. But a *single* substance such as fused silver iodide, for example, conducts readily, and is electrolysed. How are we to explain this? I imagine that the orthodox view also in this case requires us to assume that there are, normally present in the iodide, dissociated iodide and silver atoms; just as it is assumed that there are atoms of H and Cl in hydrogen chloride, or of H and O in water. Why, then, does electrolysis take place in the one case, but not in the other? The conductivity of such a substance as silver iodide is far too considerable to be explained by the assumption that it contains impurity, which, judging from the behaviour of aqueous solutions, could not possibly be present in sufficient amount to account for the readiness with which the electrolysis takes place. Nor can we, with any degree of probability, suppose that either hydrogen chloride or water in the pure state consists wholly of Arrhenius's complex inactive molecules; that silver iodide is at all events rich in simple active molecules; and that such simple active molecules are produced from hydrogen chloride only on its dilution with water. Nor do I conceive that it helps us to assume that a compound of hydrogen chloride with water is formed; it does not appear to me to be probable that an aggregate of the form $(HCl)_y \cdot (OH_2)_x$ would be more susceptible of electrolysis than the component simple molecules, and that these would be more likely to suffer dissociation when associated than when free. Unwieldy aggregates, such as Prof. Lodge refers to, break up, I imagine, if at all, not because some of the outlying atoms are not held with full vigour, nor because the atoms of the one constituent molecule are by collision of the aggregates brought close to those of the other, but because the atoms of the molecules which form the aggregate are brought into *intra-molecular* relationship; *i.e.*, the break up is not the result of the collision, but of the opportunity thus given for re-pairing to take place,* and possibly new simple molecules, *not atoms*, always result.

2. Again, it appears to me that the atomic dissociation hypothesis requires that the majority of compounds, if not all, should *per se* conduct more or less well, especially if it be admitted that ionic velocities differ; as a matter of fact, however only a very limited number can be regarded as electrolytes. Moreover, according to the orthodox view—particularly in the form in which it is stated by Arrhenius—the most active substances are those which contain the greatest number of active atoms, *i.e.*, those which are most easily dissociated. But, in point of fact, the substances which are most active—both chemically and electrically—are by no means those which we should regard as most likely to dissociate; thus, HCl, HBr and HI differ in stability to a very marked extent, yet their molecular conductivities in aqueous solution are almost identical. And a glance through the list of salts which are believed to be *per se* electrolytes is sufficient to show that these are not as might fairly be expected among the least stable, but quite the contrary: silver chloride, bromide and iodide, for example—all compounds of considerable stability—being the best conductors known, I believe, among simple electrolytes.

3. Aqueous alcoholic solutions generally oppose a greater resistance than the corresponding aqueous solutions, and solutions in absolute alcohol oppose a practically infinite resistance; yet surely it might be expected that alcohol—indeed, any neutral solvent—would screen the dissociated atoms from each other and thus render electrolysis possible.

4. If, as Prof. Lodge asserts, the orthodox view (or his version of it) pictures the dissociation of water by salt quite as easily as that of salt by water, why is conduction assumed by Kohlrausch and others to take place only through the agency of the atoms of the dissociated salt, and not at all through that of the water, except, perhaps, to judge from a recent admission made by Kohlrausch, in the case of *very dilute* solutions? Certainly, on the atomic dissociation hypothesis, both water and salt, I imagine, are to be regarded as dissociated; and moreover, it would appear probable that as the dissociated constituent atoms of water would have less chance in a concentrated solution of coming together again, conduction would take place mainly through their agency; and that in a dilute solution, for a similar reason, conduction would be affected chiefly through the agency of the salt. This conclusion is manifestly opposite to that arrived at by Kohlrausch.

5. Arrhenius asserts that the conductivity of ammonia solutions is caused by a small quantity of NH_4OH, which is increased by dilution; and in reply to Prof. Lodge's remark deprecating this statement (B.A. *Report*, 1886, p. 363), he says: "I may say in explanation that almost all chemists attribute the reaction of ammonia to a small portion of NH_4OH in it, &c." I am one of those chemists who think that it is not necessary to make this assumption, believing that the chemical changes produced by ammonia solution are due to the combined or simultaneous action of ammonia and water, but I quite agree with Arrhenius that the effect of dilution is to increase the proportion of simple or active molecules, *i.e.*, to dissociate the molecular complexes into the constituent simple molecules of ammonia. The opinion is common among chemists that the nitrogen becomes separated from the hydrogen not by direct electrolysis, but by means of oxygen primarily produced by electrolysis—in other words, that water is the electrolyte.

6. The dissociation hypothesis has not only found favour with physicists, but also with chemists, as it long seemed to afford a simple explanation of the occurrence of chemical change; in fact, the popular view may be summed up in the simple statement that simplification as a rule precedes complication. As I have more than once insisted, however, recent observations on the influence of minute amounts of third substances oblige us to admit that we have yet much to learn regarding the manner in which apparently the simplest changes

* This view is in entire agreement with one I expressed in the communication referred to; indeed, it may be considered a paraphrase of it.—O. L.

Digitized by Google

occur. In certain cases where we may almost assert that we know dissociated atoms to be present, combination or interchange does not ensue unless a minute amount of a third apparently neutral substance be present; indeed, the great problem in chemistry, which is but now being attacked, is whether it is possible for chemical change to occur between *any two* substances, be they simple atoms or more or less complex molecules. Even dissociation would seem not to be a simple function of temperature, as is well shown by the observations of Deville and Victor Meyer and Langer that the decomposition of carbon dioxide takes place in porcelain at a temperature several hundred degrees below that at which it occurs in platinum vessels. Moreover, there are not wanting chemists who assert that complication, not simplification, is the usual antecedent of chemical interchange.* No less an authority than Kekulé advocates this view, and I have recently had occasion to discuss its application in explanation of the laws of substitution in the case of carbon compounds. I do not mean for one moment to assert that anything which we know of the conditions on which chemical change depends negatives beyond question the dissociation hypothesis, but merely that it is possible, apparently, to explain the facts by means of a molecular hypothesis.

7. It appears to me that an almost conclusive argument in my favour may be based on the results of Lenz's determinations of electric conductivity and diffusivity embodied in the following table, where v is the volume percentage of alcohol, d the diffusivity, and L the conductivity; the values for an aqueous solution containing half a gram-formula-weight of potassium iodide being put = 100:—

	KI.		½ KI.		¼ KI.		⅛ KI.		1/16 KI.	
v	d	L	d	L	d	L	d	L	d	L
0	195	—	100	100	51	52	27	27	13	14
27·9	—	—	50	50	25	25	—	—	—	—
51·0	—	—	33	35	19	18	11	9	—	—
74·7	—	—	29	26	15	13	8	8	—	—

	½ NaI.		½ K_2CrO_4.		½ CdI_2.		¼ CdI_2.	
v	d	L	d	L	d	L	d	L
0	82	80	—	104	84	30	44	18
27·9	38	40	64	63	40	14	19	7·5
51·0	—	—	—	—	37	9	17	4·5
74·7	27	23	—	—	39	6	17	3·5

It will be observed that the numbers run strictly parallel, except in the case of the cadmium salt; and here the exception proves the rule, as it is established, beyond doubt, by a variety of consistent observations that the cadmium salts are of exceptionally complicated molecular composition. I entirely fail to see how we are to explain liquid diffusion by means of the atomic dissociation hypothesis. But if we assume that the water molecules are in motion, and that having an attraction for the molecules of the dissolved body they necessarily tend to drag them forward, the phenomena are of the same order as those of conduction on my hypothesis. The diminution in conductivity and also in diffusivity as the amount of alcohol is increased is most striking. If the solvent be neutral the substitution of alcohol for water should have little influence; but if, as I suppose, the solvent be active, alcohol being far less active than water, the effect to be expected is precisely of the nature of that observed.

8. With regard to Prof. Lodge's remark, "It is not easy to imagine why his molecules should be travelling past each other in the fluid," it is admitted by the orthodox that the E.M.F. gives direction to the atoms. Why, then, should it not also give direction to the moving molecules if these are still possessed of "residual affinity"—*i.e.*, if some portion of the original charge of the atom be still unneutralised? He then adds, "nor why, even if they did, this fact should assist their previously incompetent forces to disrupt each other." Let me put a case. Imagine a couple of individuals holding each other by the hand to waltz rapidly round a room, and suppose a second couple to do the same: if, as the couples passed each other, one of the individuals were to grab at one of the members of the other set, might not the members of the one or the other couple part company?

9. Ostwald's remarkable contributions to our knowledge of molecular conductivity appear to me to bear continuous testimony to the existence of such an influence of molecule upon molecule as that I have pictured. I have given numerous illustrations from his work in my Royal Society paper, but I may here call attention to his numbers for hydrocinnamic, cinnamic, and phenylpropiolic acids:—

	v=32.	64.	128.	256.	512.	1024.	2048.	4096.
Hydrocinnamic Acid ..... $C_6H_5.CH_2.CH_2.CO_2H$	2·25	3·14	4·40	6·08	8·42	11·55	15·71	20·92
Cinnamic Acid. $C_6H_5.CH.CH.CO_2H$	—	—	—	7·55	10·37	14·18	19·18	25·28
Phenylpropiolic Acid ..... $C_6H_5.C.C.CO_2H$	27·66	35·29	43·67	51·98	59·13	64·56	67·96	69·56

The numbers show that the "activity" of the acid increases as hydrogen is withdrawn. On the orthodox view the ions are *H* and *the acid minus H*; but it is difficult to conceive that the affinity of the negative ion for H should diminish as that ion becomes deprived of hydrogen, and that that acid should be the strongest—*i.e.*, conduct best—because most dissociated, which it is to be imagined would be the least ready to part with hydrogen.

10. Arrhenius certainly bases his conclusion on the orthodox view of atomic dissociation, but in his calculations makes use of the conductivity values determined by himself or Kohlrausch; it seems to me, therefore, that his results are in the main independent of any theory of the nature of electrolysis. To use his words, "L'activité electrolytique se confonde avec l'activité chimique;" or, to put it in another way, which much of our chemical experience appears to warrant, the formula by which Ohm's law is expressed

$$C = \frac{E}{R}$$

may also be used as representing the law of chemical change, C being the amount of change and E the intensity of the total chemical effect. An argument based upon electrolytic values may therefore be expected to be in agreement with chemical experience.

In conclusion, I would add that I urge these pleas on behalf of my hypothesis with the greatest diffidence, feeling that I am unfortunately unable to fully appreciate the force of the mathematical and physical arguments. I do think, however, that in framing our conceptions we may, perhaps, have been too much guided by statistical principles; it is quite open to question whether the *atoms* in molecules are in that state of unrest—are perpetually changing places in the manner in which our fancy has allowed us to picture them to be. We have yet almost everything to learn regarding inter-atomic structure, and everything regarding intra-atomic structure. It is impossible at present to quantify peculiarities and relationships which are patent to the chemist, but these must be taken into account; and for this reason it is all important that chemists and physicists should co-operate. These discussions must be of great value in bringing us together, and in enabling us to understand each other. Our thanks are due especially to Prof. Lodge for having so happily devised a means of promoting discussion.

20th August, 1887.

* This is in harmony with the "third view" of electrolysis set forth in my paper.—O. L.

INCANDESCENT LAMP MANUFACTURE.—XXIII.

BY J. SWINBURNE.

Testing (concluded).

Testing the life of lamps is a very difficult matter. No accurate or useful tests of the life of lamps has yet been made, though considerable trouble and expense have been devoted to this object.

The failures in these cases have been due to misunderstandings as to the proper methods of testing lamps, so that though great care has been bestowed on the work the results are, unfortunately, of little value.

In testing lamps for long periods two things are to be considered, the breakage of the carbon and the diminution of light either through the resistance of the carbon rising or through the bulbs being blackened.

To find which of several types of lamps has the longest life at a given efficiency it is necessary to have a source of perfectly constant electromotive force at hand. It is evident, for

Digitized by Google

instance, that running a lamp for a month at ·3 candle per watt is not the same as running it for two weeks at ·25 candle per watt and two at ·35 candle per watt. Until we have tests of lamps run till they break at one constant efficiency we cannot tell the best efficiency to run lamps. Even if we had the results of such experiments they would be of little value, because in ordinary installations the electromotive force is not constant; so that a lamp which would run for 1,000 hours on a circuit in which it gave a mean efficiency of 3 candle per watt, varying from ·25 to ·35 candle per watt, would not last so long on a circuit which gave a mean efficiency of ·3 candle per watt, varying from ·2 to ·4 candle per watt. To talk of the life of lamps as is usually done is absurd.

The commercial value of lamps of different types can be approximately obtained by imitating the conditions. There is little doubt that there is a certain temperature below which a carbon will last practically for ever, and above which it will soon break. This temperature varies with different kinds of carbon, and no doubt also depends on the difference of potential between the terminals, and on the thickness or mechanical strength of the carbon. There is a sort of silent discharge, which increases very rapidly at one temperature or one electromotive force in a lamp. This can be shown by putting a third terminal with a galvanometer and performing the experiment devised by Mr. Edison. Though the best efficiency to run lamps cannot be determined, as it depends on the installation, it is possible to find which of several types of lamps is the best. Several lamps are taken, and carefully measured at the same efficiency. They are then arranged in parallel on any convenient circuit. If the lamps are not of the same electromotive force resistances are inserted, so that all need the same electromotive force on the terminals of the lamps and resistances to give the same efficiency. The whole of the lamps are then slightly overrun to an extent varying according to the government of the engine. Those that break last are evidently the best lamps.

Exhaustive tests of this sort carried out on lamps of different makers and of different types would be of great value. The writer has carried out a considerable number, but his were not to determine which maker made the best lamps, but to see which type was the best. In all cases he found that amyloid carbons were good, though silk seemed better, this advantage being, however, compensated by the difficulty of working silk. In most cases—in fact, in practically all—a low-resistance electromotive force lamp was better than a high.

In such tests the lamps must of course be run at the same efficiencies. The American tests were made with the lamps at different efficiencies. This method only tests lamps for breaking. If a lamp's resistance increases, its efficiency falls so that it protects itself to some extent. The lamps should therefore be tested every now and then to see that there is no alteration of resistance. A lamp that runs up in resistance may be considered as broken, because it is worse than useless, for on an installation it gives very little light in proportion to the power it consumes, and people do not think of replacing it. This source of error can be avoided by putting some of the competing lamps in series and some in parallel. Thus, if two types are being tried against each other, one set is arranged with the types in parallel, so that if one rises it protects itself, and if one falls it is overrun and broken; and one set is arranged with the types in series, so that one that rises in resistance is more overrun than one that remains constant or one that falls. A new carbon that has been insufficiently flashed falls in resistance first, and rises again later on, so that by testing at any part of its career a lamp can be sent out to rise or fall with age.

Profs. Ayrton and Perry and Fleming read very interesting papers at the Physical Society in 1885, in which they consider the question of the most economical efficiencies for incandescent lamps. The chief difficulty in such questions is to get accurate data, and the errors arising from the inaccurate and unreliable data are so great as to make the conclusions of no practical value. Before problems dealing with incandescent lamps can be treated mathematically the term candle-power must be defined, as already explained. The writer would, with diffidence, propose his definition as simple and practical.

The question of the life of lamps with alternating currents has never been properly investigated. There is reason to suppose, however, that alternating currents are not so good as direct. In the first place, the extreme difference of potential between the terminals of the lamp is very much greater with alternating currents, so that there is very much more tendency to visible or invisible discharge with a lamp of given resistance. A lamp with a thin carbon run on an alternating circuit with a given electromotive force or electro-dynamometer reading, gives more light and is more overrun than a thick one. This is because the thin carbon does not remain at a uniform temperature corresponding to the average power spent, but follows the rise and fall of electromotive force to some extent. The carbon is hottest just after the highest electromotive force has been reached. Thus, if a thick carbon which cannot follow the changes of electromotive force runs at an efficiency of ·3 candle per watt, a thin one will apparently run at a higher efficiency. If the candle-power were proportional to the power, the average efficiency of the thin carbon would also be ·3 candle per watt, but as the light increases more rapidly than the power, it runs at a higher efficiency, and gives more light. The life of the lamp does not depend, however, on the average efficiency, but on the highest temperatures the carbon reaches, so that on an alternating current a lamp should only be run so that its highest efficiency corresponds to the normal efficiency on a direct current circuit, so that its average efficiency must be lower. It seems at first sight paradoxical that the thin carbon should, with a given power, give a higher efficiency on an alternating current than on a direct, and should therefore need to be run duller, not till it is at the same efficiency, but till it is at a lower efficiency in order to last as long, but a little consideration of the points here brought forward will show that it is so.

At one time the writer thought that the resistance of carbon varied with the current density as well as with the temperature; but further experiment seems to show that this is not the case. The resistance of carbon falls with the rise of temperature till the carbon reaches the temperature corresponding to about ·3 candle per watt when the resistance is stationary, above this temperature it rises again. The resistance is sufficiently constant to be taken so in considering alternating currents. The decrease of resistance of carbon with rise of temperature is sometimes supposed to be quite anomalous, but many other bodies, such as organic compounds, do the same.

The next difficulty with alternating currents is their measurement. Apart from the fact just noticed, lamps are apt to be overrun because voltmeters have self-induction, and therefore read too low. If a dynamometer, calibrated by a direct current, were used to measure the electromotive force, it would be accurate for incandescent lamp work if it had no self-induction, but its self-induction would make it read too low. To avoid this error, the voltmeter must be made of low resistance, and a resistance made without self induction must be put in series with it. Such instruments as a Siemens dynamometer wound as a small current ammeter, with a resistance in series to make it a voltmeter, and a Siemens ammeter, if its wire is not too thick, may be used in alternating current incandescent lamp work, and the currents may be treated as if they were direct—that is to say, the power may be obtained by multiplying the electromotive force as read on the voltmeter by the current as read on the ammeter. The Cardew voltmeter may be used also, and as its self-induction is probably inappreciable, it is, perhaps, the best instrument for the purpose. If it has any error due to its heating and cooling rapidly, it is of the same kind as that of the lamps, so that such an error is beneficial. It is needless to remark that these instruments may only be used on the lamp circuit itself; a dynamometer voltmeter or ammeter, or a Cardew instrument must not be used on the primary circuit of an induction coil, for instance, or anywhere where there is self-induction in the circuit. The dynamometer or electrometer connected as a watt-meter is the only instrument available, and even this demands certain precautions.

Conclusion.

One or two points only remain to be mentioned before taking leave of this subject.

The methods of making fancy or coloured lamps have already been described by Mr. Cherrill, who has had considerable experience in the matter, and in incandescent lamp work generally (*The Electrician*, April 8, 1887). The writer has also used negative varnish, with aniline colours dissolved in it. One or two dyes will not dissolve in varnish, but as the dyes are so very numerous this is a matter of little importance. The writer has used a solution of gelatine in acetic acid as a solvent, and this in many cases gives very good results.

Messrs. Zanni and Shippey have taken out a patent referring to lamps with ornamental globes. One form is made with one side clear and the other opal, so that when the lamp is used for such purposes as lighting billiard tables, the opaque side acts to some extent as a reflector. They also make lamps of corrugated glass so that the light is more diffused.

Messrs. Woodhouse and Rawson deposit silver on one side of the lamp, so the whole of the light is thrown in one direction.

Lamps are apt to be broken in transit if not carefully and properly packed. If the lamps are in large quantities they should be packed in casks, as porters are apt to drop boxes and break lamps, but they roll casks. Smaller quantities should be done up in small light boxes that can easily be lifted with one hand.

THE ELECTRICAL CONDUCTIVITY OF SOLID SALTS UNDER GREAT PRESSURE.—A paper by L. Graetz on the above subject has recently appeared in the *Repertorium der Physik*, of which the following account is given in the *Abstracts* of Foreign Periodicals issued by the Institute of Civil Engineers:—It is well known that the metallic salts in a solid state offer at low temperatures a high resistance to the electric current, but begin to conduct at temperatures even far removed from their fusing point, and that the conductivity increases with further rise of temperature. As regards the electrical resistance of such salts when in solution, this may in some measure be identified with the resistance presented to the mechanical movement of the electrified molecules; and it should therefore follow that the salts in a molten condition would act as conductors of electricity; but the fact that they begin to conduct before this change of condition takes place points to some other connection between electrical conductivity and molecular motion, a conclusion arrived at by Kohlrausch from his experiments on iodide of silver, where no sudden change in its resistance was found at the passage from the solid to the molten state. If, however, electrical conductivity of such salts be assumed to follow on the same lines as thermal conductivity—that is, to be a function of the frequency of molecular collision—then subjection of the solid salt to pressure should alter its conductivity in the same direction as has been observed to follow increase of temperature. The author's experiments, which have evidently been made with the utmost care, most conclusively confirm his arguments thus set forth. The screw press, by means of which an estimated pressure per square inch of about 700 atmospheres could be obtained, consisted essentially of a plunger working in a cylindrical hole, the sides of each being well lacquered, and a sheet of mica inserted to insure insulation between the two, so that the end of the plunger and bottom of the cylinder alone formed the electrodes, the distance between them being given by an index suitably affixed. The substances under examination required most careful desiccation, the completeness of which process was beautifully indicated by the behaviour under the electrical test; thus, if the salt were not free from uncombined water, the resistance was found gradually to increase after the application of the pressure, owing to this water being slowly expelled to the surface, and on suddenly releasing the pressure a great decrease in resistance followed as a result of the water re-entering the capillary cavities; on the other hand, with the salt perfectly dried, the opposite result was noticed, owing to the less intimate contact between the electrode and the salt.

BRITISH ASSOCIATION PAPERS.

ELECTRICAL PAPERS TO BE PRESENTED TO SECTION A.

The following is as complete a list as it is at present possible to give of the electrical papers to be read in Section A at the forthcoming meeting of the British Association in Manchester:—

A.—ELECTRICITY.

Mr. GLAZEBROOK, F.R.S., will present the report of the Committee on Electrical Standards, to which there will be one or two interesting appendices, including an unpublished chart by Prof. FLEMING. This report may give rise to discussion.

Dr. LODGE, F.R.S., will present the report of the Committee on Electrolysis. This will be considered at a joint sitting of sections A and B, very probably on Saturday, 3rd September, as an animated discussion is expected. Several papers in connection therewith will be read, including one on the Electro-deposition of Alloys, by Prof. S. P. Thompson.

Messrs. HALDANE GEE, HOLDEN, and LEES, of the Owens College, will have a paper on Electrolysis and Electrolytic Polarisation.

Mr. GEE will read a paper also on a Comparison-Magnetometer, which he will exhibit, and will join Prof. STROUD in a paper on a null method in Electro-calorimetry.

Sir WM. THOMSON will exhibit his deci-and-centi-ampere balances, and read a paper on their application to measure the E.M.F. of a single cell.

Mr. PREECE, F.R.S., will read papers on the Coefficient of Self-induction in Telegraph Wires and on Electrical Induction between Wires and Wires, the latter being in continuation of a communication made last year to the section.

Prof. EWING, F.R.S., and Mr. LOW have papers—1. On the Magnetisation of Iron in Strong Fields; 2. On the Magnetisation of Hadfield's Manganese Steel in Strong Fields; 3. On the Influence of a Plane of Transverse Section on the Magnetic Permeability of Iron.

Profs. THORPE, F.R.S., and RÜCKER, F.R.S., will give further details of their new magnetic survey.

Mr. A. P. TROTTER will read a paper on the production of a constant current with varying E.M.F. from a dynamo, and will exhibit a dynamo constructed on the principle he wishes to utilise.

Prof. LAMB, F.R.S., will read a paper on the theory of electrical endosmose.

Dr. E. HOPKINSON has a paper on the general theory of dynamos.

Mr. W. LANT CARPENTER offers a paper on certain suggested improvements in cable signalling, with a view of greatly increasing the speed of signalling.

Prof. S. P. THOMPSON has papers on (1) The Temperature Coefficient of E.M.F. in Accumulators; (2) the Prediction of the Tractive Force of Electromagnets.

Mr. KILLINGWORTH HEDGES suggests an improvement in the construction of secondary batteries.

Mr. J. SWINBURNE offers a paper describing Some Experiments on Standardising by Mercury-Voltameters.

Mr. GLAZEBROOK, F.R.S., will exhibit an induction-coil made by Mr. Higgs.

Prof. SCHUSTER, F.R.S., will communicate a paper on magnetism, by Prof. SCHERING.

Prof. PRITCHARD, F.R.S., has a paper on Sir Howard Grubb's Electrical Control of Telescope Driving Clocks.

Prof. BALFOUR STEWART, F.R.S., will communicate the Report of the Committee on Magnetic Observations.

Hon. R. ABERCROMBY has a paper on the different varities of thunderstorm, and will suggest a scheme for their systematic observation in Great Britain.

Besides the above a number of electrical papers will be read in Section G.

THE BRITISH ASSOCIATION.

After an absence of more than a quarter of a century the BRITISH ASSOCIATION will next week revisit the industrial capital of the British Empire. This is the third occasion on which this annual gathering has assembled at Manchester, the first being in 1842, and each time the event has been a notable one in the annals of the ASSOCIATION. Partly because of the central position of the place, but chiefly, no doubt, because of many local celebrities whom Manchester has produced, these visits of the BRITISH ASSOCIATION have invariably aroused an interest and even an enthusiasm which differ not only in degree but in character from the respectful and formal hospitality that this representative body of scientists is in the habit of receiving elsewhere. To mention JOULE, and DALTON, and FAIRBAIRN, whose names are intimately associated with the great cotton metropolis, is enough to account for this distinguishing characteristic of its inhabitants. This year a man hardly less eminent in his special walk of science than any of those just named will occupy the presidential chair, and Manchester claims him as her son. The meeting was there in 1842, when, in the place of DALTON, whose health was too feeble to accept the position to which he was entitled, Lord FRANCIS EGERTON presided. The second meeting was presided over by FAIRBAIRN, and is remembered as the largest which the ASSOCIATION has ever yet commanded. But next Thursday's meeting promises to outstrip all previous records both in respect to the scale of liberality on which the preparations are being made, and the number of visitors who will profit by them. The fact that Sir HENRY ROSCOE is to be presiding genius of the occasion seems to have spurred the Manchester folks to testify that not only can they produce great men, but that they know how to welcome others of the same stamp, come whence they may.

It happens, too, that the Manchester Jubilee Exhibition is still open, and it will be an attractive as well as useful feature to many of the intending guests. The scientific colleges, societies, and clubs, of which the city possesses a remarkable number, will all be at the disposal of members of the ASSOCIATION, and the amplest provision has been made for their entertainment and comfort. This is what we might expect of a place which can boast of Owens College and Victoria University; but all the same it is not invariably the case that citizens so highly favoured rise to the level of their privileges; and it is one of the most encouraging indications of the growing reputation of scientific pursuits among a people whose chief avocations are manufacture and trade, that the principal inhabitants of Manchester, supported by the whole population, are throwing themselves heartily into the work of giving a fitting reception to an association whose chief object is the advancement of science. But for this, probably the BRITISH ASSOCIATION would not have been able on the present occasion to have taken a step forward in making these gatherings more international than they have hitherto been. Upwards of 100 foreign men of science have accepted invitations to become guests during the forthcoming meeting. According to *The Times* the selection has been made by ascertaining of the various scientific societies in this country the names of those whom they regarded as the most representative men abroad in their own special departments. The result is that a brilliant array of foreign scientists will be present, especially in the branches of chemistry, physics, and biology, such as has never before graced the proceedings of this or any other learned society.

It is interesting to look back to the *Transactions* of the Society to see the part played by electrical matters in these previous meetings at Manchester. Of those who contributed to the business of the ASSOCIATION in 1842 almost the only one still with us is JOULE, who then read a paper on "The Electrical Origin of the Heat of Combustion." A paper of some interest at the present meeting, when the Chemical and Physical Sections will discuss the Report of the Committee on Electrolysis, was read in 1842 by Prof. SCHÖNBEIN on "The Electrolysing Power of a Simple Voltaic Circle." Various papers were also read at that first meeting on "Terrestrial Magnetism." Coming to the meeting in 1861 we find a large number of papers, showing that electricity was becoming of greater importance in scientific circles. Several papers related to earth currents and similar phenomena, and some others to the magnetic action of compasses. It was at this meeting that Mr. LATIMER CLARK and Sir CHARLES BRIGHT read their now historic paper on "The Formation of Standards of Electrical Quantity." The subject never after this was allowed to drop, and the result was the British Association "Committee," which has done such excellent service on this subject for our science. The late FLEEMING JENKIN read a paper at this meeting on "Permanent Thermo-electric Currents in Circuits of One Metal." Mr. J. P. GASSIOT, F.R.S., read a paper on "The

Digitized by Google

Deposit of Metals from the Negative Terminal of an Induction Coil during Discharge and Vacuo." C. W. SIEMENS read one on "An Electrical Resistance Thermometer for Observing Temperature at Inaccessible Situations." It may also be worthy of notice that the president of this year, Sir H. E. ROSCOE (then Mr. H. E. Roscoe), together with R. ANGUS SMITH and Dr. E. SCKUNCK, reported on the recent progress and present condition of manufacturing chemistry in the South Lancashire district. Then, as now, the magnetic survey of Britain seemed to possess considerable interest for a certain section of the members, and papers on this subject were read at the meeting.

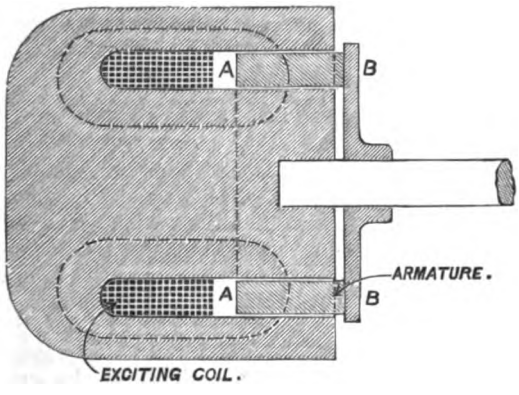
CORRESPONDENCE.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: About a year ago I was thinking of a means of generating a current of electricity on a plan identical with that of the Forbes machine. Prof. Forbes had already produced his dynamo, but I had not heard of it.

In this state of ignorance I wrote to you describing an apparatus with toad-stool shaped field-magnet, differing only from the arrangement now shown in the armature, which



Longitudinal section through axis.

I represented by a wire, which might be considered as a piece of the armature now shown projecting into the field space and parallel to the axis. I did not describe any sliding contacts, which would obviously require to be placed against each end of the armature at A and B, but asked you whether any E.M.F. would be produced in the wire when revolved. With your permission I will quote the following from the private reply which you kindly sent me:—"Your difficulty as to the generation of E.M.F. by a uniform field arises from confining your attention to 'a conductor' instead of to the circuit of which it forms part. If the circuit be wholly within the uniform field, then no E.M.F. is generated so long as it moves in any direction while remaining parallel to itself or to its own plane; in any other case the number of lines traversing the circuit changes its value and a current is generated. If the circuit be not wholly within the field, any motion of that part of the conductor within the field will obviously change the number of lines passing through the circuit, save in the particular case when the motion is parallel to the lines themselves." In consequence of this reply I lost confidence in my idea, and later on, when I got possession of Kapp's "Electrical Transmission of Energy," I was a little surprised to see a description of my castaway device, the non-polar dynamo.

Now, Sir, I am convinced that the statement that the "number of lines passing through the circuit must change in order to have a current" is not true of this dynamo; nevertheless Mr. Scattergood tenaciously upholds its correctness. From his last letter I quote, "There was a slip in my last letter, where I said that the number of lines passing through the circuit varied from zero to a maximum and back to zero. Of course the number increases (or decreases) continuously at each revolution." This altered statement of his view is even more incomprehensible than the first. There are only three ways of looking at it. At the end of each complete revolution and the commencement of the next the conditions are precisely similar. That is undeniable. And I want to know what becomes of the lines which have entered the circuit during each revolution. (1) Does their number continuously decrease at the same time and rate as it continuously increased? "Which is absurd," as Mr. Euclid would have said. If not, (2) do the lines which have entered during a revolution instantaneously quit the circuit as the next revolution begins? Zounds! What an E.M.F. that would produce—infinite is the word for it. But this is worse than the first alternative. (3) Does the number of lines in the circuit go on increasing while the machine is kept running? If so, then when the motion ceases the magnetism in a few moments disappears, there is a stampede of all the accumulated lines out of that circuit. Fortissimo! What happens to the dynamo? "Of course" I would counsel Mr. Scattergood to relinquish this theory.

Had not Mr. Thompson stated in his last letter that he had carefully read my last and previous letters, I certainly would not have thought it so. I think if he re-reads the 6th and 7th paragraphs of my last letter, he will perceive that he has missed the chief points, and attached far more significance to others than my language warrants.

I will briefly recapitulate the main points I have put forward during the discussion, as I do not appear to be properly understood:—(1) I assume there is a reaction equal and opposite to the pressure exerted by Forbes's armature when working which tends, through the medium of what is called "lines of force," to drive something round with it. (2) That that something (in which this reaction has its seat) is either the exciting coil (as Mr. Thompson has it) or the iron of the field magnet; or, as is most likely, that portion of the galvanic circuit which is distinct from the armature and connected with it by sliding contacts. (3) That it may in a slight degree be due to mere molecular friction in the iron of the magnet, &c., due to the movement of the lines therein. (4) I have demonstrated (paragraph 6 last letter) that it cannot possibly be due to Foucault currents. Here I would ask Mr. Thompson how it is, if he read the paragraph referred to, that he says: "Mr. Snowdon knows well that the Foucault currents are by far the most potent, if not the only cause, &c." (5) It has also been shown that if the armature drives the lines round with it, they must cut the stationary portion of the circuit in the opposite direction, and to the same extent that they would have cut through the armature, so that the E.M.F. is the same either way. (6) I hold that E.M.F. current or no current is invariably produced when lines traverse a conductor, whether the number of lines in the circuit changes or not.

I have always regarded as feasible the doctrine that the lines are *quasi* fixed to the exciting coil, but that the pressure of the lines of force is entirely confined to the conductors in which they are generating current is far more likely to be true.

I may say that when I first sought information on this point I was endeavouring to think of a means whereby to obtain high E.M.F. in a non-polar machine.

Various devices more or less simple suggested themselves. One was especially simple, and theoretically, at any rate, involved no diminution of efficiency; but in all cases the objectionable sliding contacts presented themselves, and it was in endeavouring to dispense with them that I wanted to find that the exciting coil really held the lines fast.

Mr. Sprague's views on the subject of magnetism seem to me the most advanced with which I have made acquaintance, but I do not get the information I want from his theory.

Of course, it is the stationary conductor in Forbes's machine which opposes resistance to the circulation of the lines; then, if suitably arranged apparatus were employed, it should be

Digitized by Google

possible to observe a deflection of this part of the circuit under the stress.

I would be happy to confer privately with any gentleman who has the leisure and inclination to make the investigation. —Yours, &c., R. SNOWDON.

Staveley, Aug. 22, 1887.

[The letter quoted by our correspondent (and the accuracy of which we, of course, fully maintain) was written in response to a private communication, in which he had expressed his inability to understand how a current could in any case be generated by the motion of a conductor in a uniform field. When Mr. Snowdon states that he is *now* of opinion that "an E.M.F. is *invariably* produced when lines traverse a conductor, whether the number in the circuit changes or not," he goes to the other extreme, and commits himself to an assertion which is capable of easy disproof. Mr. Snowdon's difficulties evidently arise chiefly from a laudable anxiety to obtain a physical conception of the nature of the action which takes place in a conductor traversing a magnetic field. In this desire he has our entire sympathy, although we venture at the same time to think that he will do well to base his working theories upon purely experimental evidence, and to relinquish, for the present, the attempt to understand the *modus operandi* of the generation of E.M.F., at least until something more is known of the nature of magnetism and of electricity. We must, of course, feel very sorry if our reply to our correspondent's letter of twelve months ago has dissuaded him from perfecting any advance either in the theory or the practice of the construction of dynamos; but we must also remind him that his letter said nothing about such a design as he here refers to, but was confined to the query above quoted and to a question about magnetic leakage.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Voice in his last letter correctly states the conditions on which I laid stress in a previous communication, namely, that to produce current by the machine under discussion at the time it would be necessary for the conductors to be relatively influenced by the field; and, indeed, if it were not so, it would be impossible to conceive how two equal and opposing forces could give any dynamic effect. But again I must ask, what does this pivot arrangement prove? The fact of the pivot being cut by fewer lines of force, or if Mr. Voice likes it, by none at all, only presents these conditions with greater force.

Mr. Voice is delighted at the prospect of catching me napping. He says I have clearly contradicted myself; but is there not a little contrariness in the method by which Mr. Voice arrives at this conclusion? Did I not call both the disc and the wires conductors—the former a neutral conductor to distinguish it from the others? Where was the reference to the disc, seeing that there was a full stop between the two sentences? And may I ask why, if there were two possible interpretations, Mr. Voice should be so anxious to take that which would naturally make nonsense?

Mr. Voice then proceeds to set forth a problematical experiment as a subject for discussion. He first informs us he has not tried it, and then winds up by saying "it is impossible to explain the action on the rotating lines of force theory." But what action? Is it an assumed action of Mr. Voice's?

Referring to the two magnets revolving in opposite directions (Fig. 1), he says: "What become of Mr. Thompson's rotating lines of force now? Are they crumpled up, doubled up, or torn asunder like bits of string, or are they infinitely elastic, and capable of unlimited twisting?" But what if nothing of the kind occurs, if the lines of force belonging to the magnet as a whole do not form—that is to say, if the conditions now established are not conducive to the transmission of the magnetic force constituting the greater field—and what if the two separate magnets become in consequence individually stronger?

I put these questions rather as a suggestion than a solution, as I can conceive of two or three other equally probable assumptions, one of which would lead to the production of the stationary field that Mr. Voice is so bent on; but even if this latter were correct, there would be an intelligible reason for such phenomena which could only exist under the very peculiar conditions that Mr. Voice has presented. I do not think that much is to be gained by discussing the problem in question in its present stage, but it will not be difficult to answer Mr. Voice's last interrogatories on the basis of the suggestion I have put forth.

Mr. Voice says:—"Assuming for the moment that the lines do revolve in opposite directions with the magnets (a perfectly feasible assumption under the action described above), how is current generated in this experiment?" I reply that if the magnets were revolving in the same direction, were of identical form and strength, and the discs in symmetrical positions, there would, on my previous showing, be no current, for the simple reason that the E.M.F.'s would be equal and opposed, whereas, on the other assumption, these forces not being equally opposed, current might be expected.

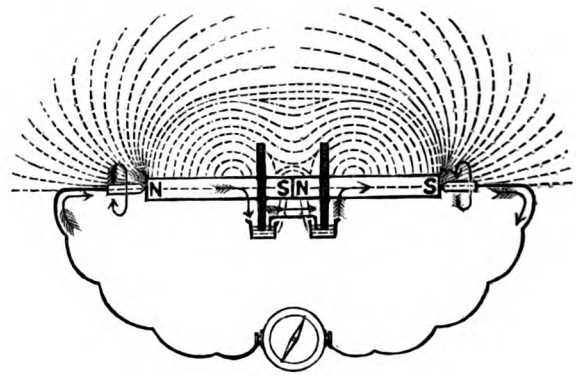


FIG. 1.

Mr. Voice asks, "Where is the fixed conductor that can even remotely be supposed to be cut by any moving lines of force?" I must refer him to the illustration given, which will show him that his bridging wire will be directly cut, and that if the magnets be made to revolve in the directions indicated by the arrows, a current will be set up in the circuit as traced.

Having replied to Mr. Voice's letter, I will now proceed to ask him for some more definite information regarding his own theory. We are still in the dark as to the *raison d'être* of his stationary magnetic field, nor has he told us how, in his opinion, current is produced in any of the machines under discussion. I understand that he will give us this last piece of information in your approaching issue; but what about the field? If Mr. Voice believes that the forces constituting the field of a permanent magnet are maintained, though not caused, by exterior influences, I am quite in agreement; but if he holds that the form and distribution of the field are both due to these influences, I must differ, and my reasons for objecting to such an assumption would be that, inasmuch as a permanent magnet retains the distinctive character of its field in whatever position it be placed, it is evident that any exterior forces capable of effecting this would have to possess not only a characteristic and defined action in accordance with the effect produced, but would have to act in every direction throughout space, whether the magnet be there or not, the result of which would be that these forces would lose their definitive character. We are, then, driven to the conclusion that the form and distribution of the field is a function of the magnet itself, and is dependent on some unknown quality possessed by it, and from this it would follow that in the case of an electro-magnet, when the current ceases to pass round the coils, the iron loses its magnetism because it does not possess that quality by virtue of which the magnetic forces may be maintained under conditions of distribution conducive to their equilibrium. I will further ask Mr. Voice what in his opinion occurs when a permanent magnet is shifted from one place to another? Does the field constituted of molecules under strain or in action move bodily with the magnet, or do only fresh molecules come under its influence?

Digitized by Google

If the latter hypothesis were true, each time the magnet was shifted it would expend force on a new field of inert molecules, and hence, by continually moving it backwards and forwards it would very soon lose all its magnetism. Again, if it be assumed that its force is derived from an external source, how is it that magnets do gradually lose their magnetism even when stationary?

But there are other technical difficulties attending such a theory. A conductor moved across the end of a permanent magnet would cut a stationary field, just as I conceive it ought to do; but if the magnet be moved instead of the conductor a different action would result, the molecules of the conductor would not in this case be cut by the field, inasmuch as the field conceived in the material sense would not move, hence the conductor would only be subjected to a strain varying with the intensity of the passing field, and if this field were of even strength or symmetrical, as in the case of a disc machine, the molecules of the conductor would not receive their necessary oscillations.

I will now apply the foregoing to Mr. Voice's theory of an independent field. Let us take an ordinary magnet and place it at A (Fig. 2), as shown. Now, if it be moved to B it is evident that as the field moves with it its motion must be due to the influence of the magnet, and this influence will be exerted in a transverse direction, as shown by the arrow; but the field itself is in a state of tension, or bound, so to speak, together as a whole—hence the influence referred to has been exerted on all the lines passing through the magnet. How is it, then, that the magnet when revolving axially does not exert this same transverse influence on its field, and so carry it round? Perhaps Mr. Voice will explain.

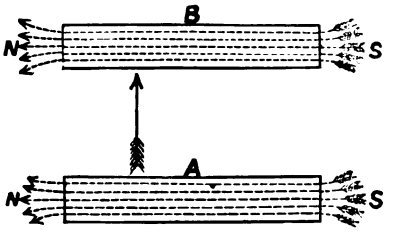

Fig. 2.

I have gone somewhat fully into the question respecting the nature of a magnetic field because Mr. Voice in his last letter stated that it was stationary, and the idea was so inconceivable to me that I had previously—and perhaps without sufficient reason—assumed that his field would not be held stationary by any external conditions, and would consequently be as free to revolve round the magnet as the magnet within it; and this is why I have accused him of asserting in principle the erroneous maxim that the nature of a force can be transformed without the necessary interposing and reacting agent.—Yours, &c.,

N. G. Thompson.

4, Queen Victoria-street, E.C.
Aug. 24th, 1887.

M. MENGES' METHOD OF REGULATING DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last issue, page 305, you published a note containing some ironical remarks concerning my electric regulating method. The author of this note was apparently very hurried when reading the account of the experiments I made in Paris, for what he said shows clearly that he totally misunderstood my invention.

Firstly, I may assure you that your French contemporaries are not at all "under the impression that this is the only electrical governor in existence;" on the contrary, they know very well that there are a great many electric regulators, and that the apparatus I used is *not* a regulator in the usual sense of the word, because the current to be regulated does not circulate therein.

In respect to myself, I may add that I am perfectly acquainted with Richardson's, Willans', and many other regulators, and therefore I know that all those regulators act only *by means* of the variations in the quantity to be kept constant; therefore they *cannot prevent* variations. By using my method variation may be *prevented entirely.*

Indeed, my method of regulation is quite different to what has been done hitherto; it regulates only in the case of variations in the use of electricity—for instance, when lamps or motors are switched in or out; but irregularities resulting from other causes—for instance, a defect in the dynamo by a short circuit in some coils in the armature—will not be regulated. Now, with a Richardson or any other such electric governor the cause of the irregularity is quite immaterial, and in the supposed case the loss of electric tension will be restored for a few moments by an increased speed of the engine till the armature is completely burned, while had my regulator been used the defect would have been detected at once, and the armature saved from completed destruction, and could perhaps have been repaired at little expense of time and money.

Other distinctive features of my regulating method may be found in the April number of the *Elektrotechnische Zeitschrift* of this year (which I send you annexed by book post), where also my very successful experiments made last year at the electro-technical laboratory of Prof. Slaby in Berlin are related.

The best way to prove the value of an invention is certainly by experiments, and if you consider that, even though the idea had only been put into operation in a "somewhat crude form," as is stated in your journal, nevertheless I obtained results which could not be attained before by the best and very complicated regulators (as was duly observed by competent men), you will agree with me that this is the best proof of novelty and usefulness of my regulating method.

By inserting this letter in your next issue you will oblige—Yours, &c.,

C. L. R. E. Menges.

The Hague, 22nd August, 1887.

[M. Menges will see from a Note in another column that the misunderstanding to which he refers did not arise with us, but from the erroneous version which appeared in a French contemporary.—Ed. *E.*]

THE SUPPOSED NEW FORCE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In *The Electrician* for 19th August Dr. Shettle employs the terms "arterial blood corpuscles" and "venous blood corpuscles" (*see* p. 319). These terms are, it is true, in accordance with the language employed by medical men. When the employment of instruments of precision is requisite for the investigation of any delicate scientific subject, surely the employment of precise language is still more requisite in describing any scientific facts. Hence I should have expressed myself in the following language:—

"I ascertained the magnetic power of the blood corpuscles (discs) while in the arteries, which being charged with greater amount of oxygen gas, and less carbonic acid gas, than the self-same blood corpuscles while in the veins; and proved that the blood corpuscles (discs) while in the arteries are paramagnetic to the blood corpuscles while in the veins—a fact of no inconsiderable importance when it is recognised that the blood corpuscles while in the arteries contain a power to stimulate the nerves to a healthy vital action. This power does not exist in the self-same blood corpuscles while in the veins. These effects are produced through the double exchange of the gases—oxygen and carbonic acid—in the act of breathing, and in the transit of the blood corpuscles, chiefly through those vessels called 'capillaries' in the pulmonary and systemic systems."

I maintain that there are literally and scientifically no arterial and venous blood corpuscles. They are simply blood corpuscles, or discs, wherever they exist, and in whatever condition they occur.

The power to which Dr. Shettle refers is likely to be

Digitized by Google

magnetised vital electricity, which permeates the blood corpuscles extracted in the act of inhaling the atmosphere.—Yours, &c., E. Nock.

16, Bloomsbury-street, London, W.C., 20th August, 1887.

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 310.)

During the year 1881 the United Telephone Company were busily engaged in the work of extending their operations both in London and in the provinces. By this time the value of telephonic communication was fully recognised in commercial circles, and no difficulty was found in establishing subsidiary companies in various provincial centres. As we intend in the course of this series of articles to give an account of each of these in turn, we shall confine ourselves for the present to the history of the parent company.

In face of this manifest proof of the growth and vitality of the telephone it was almost inevitable that attempts would be made to contest the validity of the patents held by the United Telephone Company, or else to show that equally good results might be obtained by means which were presumed to lie beyond the scope of these patents. The first action for infringement was brought in the Edinburgh courts in January, 1882, against a defendant named M'Lean, who had made and sold both carbon transmitters and Bell receivers. Inasmuch as the whole case was virtually retried in the English Courts a little later, it will be sufficient for the present to state that both the Edison and the Bell patents were fully sustained, and an injunction was granted against the defendant.

A more serious attack of the same nature was made in the years 1881-2 by a company which established itself in London and commenced to develop an exchange service under the title of the London and Globe Telephone Company. The instruments adopted by this company were manufactured by Messrs. Harrison, Cox-Walker and Co., and consisted of a receiver identical with Bell's, except that a horse-shoe electro-magnet was substituted for the permanent bar magnet, and a transmitter devised and patented by the Rev. J. Hunnings.

Mr. Hunnings commenced to experiment upon telephones immediately after the British Association meeting of 1877, and carried out his investigations upon a line stretching between his own house and the Archiepiscopal Palace at York. Having failed to obtain any satisfactory results from a diaphragm carrying a point which pressed upon a metallic contact somewhat after the Reis type, he succeeded in the following April in transmitting speech by means of a row of cinders, nearly two feet in length, taken from the fire grate. Prof. Hughes communicated the results of his researches on the microphone to the Royal Society on the 9th May, 1878.

A little later, Mr. Hunnings had found that good results were obtained by the use of a quantity of granulated (not finely powdered) carbon in the form of engine coke, and he placed a layer of such particles upon a substantial brass plate covering them with a diaphragm made of platinum foil. "The reason," says Mr. Hunnings, "that I made use of this oven-made engine coke was because, taken bulk for bulk, its specific gravity was the lightest thing I could find so that sound waves could move about these particles very easily." He further insisted at the time upon the necessity of the grains being in "a perfectly loose condition," so that they could be easily shaken about. It is tolerably clear that Mr. Hunnings's own idea was that the action of the instrument was due to the variation in the number of the grains in electrical contact, as well as in what may be called the average extent of such contact of the several grains. Stress was laid upon this as distinguished from the "pressure" theory of Edison's instrument.

To Hunnings, in fact, as to Berliner, and in some degree to Du Moncel, is clearly due the credit of having constructed what were virtually microphones independently of the researches of Prof. Hughes, but to Hughes alone belongs the honour of having investigated and developed the singular virtues of loose electrical contact. Hughes was the indisputable discoverer of the essential requirements of microphonic action, even although the true theory of the nature of that action is still a matter of dispute.

Before proceeding with the story of the fortunes of the Hunnings transmitter in the hands of the Globe Company, this may not be an unsuitable place to discriminate also between the microphone of Prof. Hughes and the earlier "tension-regulater" of Edison, more especially as the Hughes microphone was scarcely mentioned in the legal proceedings which ensued *re* the Hunnings transmitter. It is frequently supposed that Edison employed the word "tension" in its mechanical sense as having something to do with the elasticity of the diaphragm which forms an essential portion of his instrument. In reality the term is employed in the somewhat loose electrical sense which was in vogue at that period, and was intended to indicate that the apparatus, by varying the resistance of the circuit, regulated, or, more strictly, varied, what we should now call the difference of potential between the terminals of the battery. The following is a description of the device in the words of Sir Frederick Bramwell:—"The tension device is made of something of semi-conductivity, lampblack, plumbago, or other materials *of an elastic character*, which can be brought nearer together, and will re-assert themselves when that which brought them nearer together is removed, and a tympan, or diaphragm, which need not be capable of inductive action—it may be of mica, for example—is caused to vibrate by the sound waves produced by the speaker, and in its vibration varies the pressure on the tension device [which] thereby possesses more or less resistance to the passage of the current." Although, as regards terminology, this language may not, according to our present lights, possess a high degree of scientific merit, yet it is a perfectly clear and unmistakable description of the nature of the device. The essential point here set forth is the use of a conducting material whose resistance by reason of its spongy (rather than elastic) nature* is capable of variation in very exact accordance with the degree of compression to which it is subjected by the sonorous vibration of a diaphragm with which it is in mechanical connection; such material should also be of high specific resistance in order that the total amount of variation in the resistance of the circuit may be sufficiently great for the purpose in view.

But the nature and degree of importance of the part played by the diaphragm in an Edison instrument constructed on these lines is more fully set forth by Edison in the specification of the patent. He says, "Many materials have been employed by me, such as metals, horn, vellum, celluloid, ivory, &c. [it is somewhat singular that he does not mention wood], but almost all of these produce a prolonged or secondary vibration from their own resonant character. *Hence the articulation is defective*, and the sound vibrations blend." [Needless, perhaps, to say that the italics are our own.] He then states that mica is employed, as being almost entirely free from these defects. The principal claim in the specification is as follows:—

"In an instrument for transmitting electric impulses by sound the combination with a diaphragm or tympanum of electric tension regulators, substantially as described, for varying the resistance in a closed circuit substantially, as set forth."

Considering the immense importance which this claim has subsequently assumed and the wide interpretation to which it has been admitted it is a little singular that greater stress has not been laid upon the confession italicised above. Edison certainly did not at the time feel satisfied with the employment of a mere "legal diaphragm;" he required, and to his greater credit he sought until he had discovered, a substance from which a diaphragm having certain specific properties of non-resonance could be made. The microphone of Hughes, upon the other hand, does not require any diaphragm at all, only it happens to be the case that it is somewhat inconvenient and difficult to make use of the apparatus without bringing in at the same time a structure which comes within the legal (though possibly not the scientific) definition of the term. We believe this to be an accurate and impartial

* This description applies to the use of plumbago, as well as lampblack, because the plumbago was applied by being rubbed upon, or dusted over, silk thread or floss, as set forth in the specification.

Digitized by Google

version of the evolution of the carbon transmitter, and while we cannot but regret that the generous intention of the discoverer of the microphonic principle has been frustrated, yet we must continue to uphold the necessity of bowing to the decision of the legal tribunals of the country as the ultimate appeal in matters of patent right. At the same time it is a pleasure to quote the language employed by Mr. Preece in a paper read before the British Association, at the Southampton meeting in 1882, and with this quotation we conclude the present chapter. After describing Edison's apparatus, Mr. Preece said :—"Prof. Hughes went a step further. He found a combination of materials that were directly affected by sonorous vibrations, which he called a 'microphone,' and he proved that the effect of the carbon transmitter of Edison was not due to any influence of varying pressure on the mass of the carbon, but was a phenomenon of loose contact. He found a new fact in nature, and he startled the scientific world by introducing an instrument which did for minute sounds what the microscope had already done for minute objects."

(To be continued.)

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 290.)

In the last paper I unwarily fell into the trap of stating that, under the condition of constant current, μ would be constant, and that therefore the case required no special notice.

This, of course, is not so, because the ratio of the surface to the mass is variable ; the point must therefore be considered.

We have from equation (6)

$$N \propto \frac{E}{R^2}, \text{ that is, as } \mu R^{\frac{1}{2}}.$$

From (7) $A \propto \frac{\mu^2 R^2}{N}$ that is, as $\mu R^{\frac{3}{2}}$, we can thus write

$$A = d_1 \mu R^{\frac{3}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1c)$$

and using square wire,

$$\mu = \frac{\sqrt{A}}{\sqrt{A} + \cdot 05}.$$

Substituting for A,

$$\mu = \frac{\sqrt{d}\,\sqrt{\mu}\,R^{\frac{3}{4}}}{\sqrt{d}\,\sqrt{\mu}\,R^{\frac{3}{4}} + \cdot 05},$$

whence $$\mu^{\frac{1}{2}} = \frac{-\cdot 05 \pm \sqrt{\cdot 0025 + 4\,d\,R^{\frac{3}{2}}}}{2\sqrt{d}\,R^{\frac{3}{4}}},$$

and $$\mu = 1 + \frac{\cdot 005 \mp \cdot 1\sqrt{\cdot 0025 + 4\,d\,R^{\frac{3}{2}}}}{4\,d\,R^{\frac{3}{2}}} \quad . \quad . \quad (2c)$$

Since μ must be less than unity, the negative sign will be taken in (2c). The total work per second will then be

$$W = c\left\{R^{\frac{5}{2}} + \frac{R}{d}\left(\cdot 00125 - \cdot 025\sqrt{\cdot 0025 + 4\,d\,R^{\frac{3}{2}}}\right)\right\}. \quad (3c)$$

In the field-magnets the section of wire is $A = e_1 \mu_1 R^{\frac{3}{2}}$, and with circular wire

$$\mu_1 = \frac{\sqrt{\pi}}{2} \cdot \frac{\sqrt{A}}{\sqrt{A} + \cdot 02}.$$

Substituting for A and solving

$$\mu_1^{\frac{1}{2}} = \frac{-\cdot 02 \pm \sqrt{\cdot 0004 + 2\sqrt{\pi}\,e_1 R^{\frac{3}{2}}}}{2\sqrt{e_1}\,R^{\frac{3}{4}}};$$

whence, by taking the rational sign,

$$\mu_1 = \frac{\sqrt{\pi}}{2} + \frac{\cdot 0002 - \cdot 01\sqrt{\cdot 0004 + 2\sqrt{\pi}\,e_1 R^{\frac{3}{2}}}}{e_1 R^{\frac{3}{2}}} \quad . \quad (4c)$$

The efficiency can now be expressed as a function of B, as before. The length of these expressions might deter many from making any use of them, but the intrinsic usefulness of a means of predetermining the electrical efficiency, especially in the design of very small machines, is undeniable. Nor need the formula here given take any unreasonable time in its application ; in fact, with the assistance of the slide rule or logarithmic tables, a set of curves such as those given in the last paper may easily be calculated in a couple of hours, whilst the systematic use of such curves would afterwards save an immense amount of time and labour.

Before commencing the design of a drum armature machine, it is necessary to correct an error in the original equations on page 479, Vol. XVIII. Here the length of winding was given as

$$2\,N\,R\,(q + \beta + \tau),$$

but the convention was before established that N should not mean the number of complete turns on the drum, but the number of wires counted round the outside ; thus, the above expression should be

$$N\,R\,(q + \beta + \tau),$$

which, followed through, alters the value of R in the ratio of $\frac{1}{2^{\frac{1}{7}}}$, and so reduces the numeric 3 6 to 3·26. There is a further clerical error in the appearance of the symbol π within the brackets in the final equation (4*a*), this quantity being absorbed in the numeric 3·26.

Since in drum armatures the section of the core is greater in proportion to the external dimensions than in rings, it will be best to increase the length in relation to the diameter, as otherwise the field-magnets would work out awkwardly deep, and so increase the coefficient of leakage.

The spindle, being of hard steel, is not considered in the magnetic conductivity of the core. Referring to Fig. 8, page 479, Vol. XVIII., the coefficients will be taken as follows :—

$q = 2 \cdot 5$	$M = 20$
$p = \frac{2}{3} = \cdot 6$	$\gamma = \cdot 8$
$\beta = \cdot 1$	$\rho = \cdot 8$
$\tau = 3$	$\mu = \cdot 8$

Taking, as before, E = 117 volts and C = 100 amperes, we get from equation (4*a*) R = 3·26 × 1·06 = 3·45, say,

R = 3½ inches,
N = 184 = 92 complete turns,
A = ·0262 square inches.

The depth of copper $\mu\beta R = \cdot 276$in., and divided into 2 layers this gives a section ·138in. × ·19in. wide.

The coefficient μ is now found to be $\frac{\cdot 19}{\cdot 19 + \cdot 05} = \cdot 79$, which is sufficiently close to the assumed value. It may be remarked here that the above rule for μ was found to agree with the practical conditions for ring armature winding, where the constant ·05 provides for both insulation covering and for the driving arms of the ring. In drum winding the same constant is retained in order that sufficient space should be provided for the insertion of driving horns at intervals between the windings.

From the number of coils it is seen that a 46 part commutator will be most suitable ; there will then be two complete turns to each section.

The total number of lines passing through the armature is

$$Z_1 = \frac{117 \times 10^6}{184 \times 1000} = 636$$

the saturation coefficient, with M = 20, will be, as before, K = 2·45.

The specific magnetic resistance is

$$R_A = \frac{\pi\left(R - \frac{p\,R}{2}\right)}{p\,q\,\gamma\,R^2} = \cdot 45,$$

thus $K\,R_A = 1 \cdot 4$.

The depth of winding will be $\beta R = \cdot 35$, and by the rule of ⅛in. per foot diameter of core the clearance = ·073, which

Digitized by Google

gives $\delta = 423$; but in order to bring this into English measure we will make $\delta = \frac{7}{16} = \cdot 436$in. The magnetic resistance R_a is now to be calculated. Finding the pole surface as before, we get

$$\frac{135}{360} \cdot 2\pi R \cdot q R = 72 \text{ square inches};$$

$$\therefore R_a = \frac{1440 \times \cdot 872}{72} = 17 \cdot 4.$$

The joint resistance $K R_A + R_a$ is thus 18·8, and the exciting power $p_1 = 636 \times 18 \cdot 8 =$ say 12,000.

The air resistance $\rho = \frac{400}{7} = 57$, and the leakage passing under the exciting power 12,000, is $\frac{12000}{57} = 210$, giving $Z_2 = 636 + 210 = 846$. The section of the field cores is thus $AB = \frac{846}{18 \times \cdot 8} = 58 \cdot 8$ square inches.

The length of the armature is $2 \cdot 5 \times 3 \cdot 5 = 8 \cdot 8$in.; the best practical arrangement would therefore be to have two bars, each 4¼in. × 7in., set edgeways, with ⅜in. or ½in. gap between them; the total section would then be 59½ square inches.

To determine the length of the cores μ_1 can be assumed, as before, at ·7; the depth of winding $d = \frac{7}{4} = 1 \cdot 75$in., and the length of a mean convolution $l = 32 + 1 \cdot 75\pi = 37\frac{1}{2}$in., giving the preliminary section A = ·0055. The circular wire corresponding to this section is ·0836in. diameter, which gives $\mu_1 = \cdot 71$.

The number of turns per inch will be

$$n = \frac{\mu^2 d}{A} = \frac{\cdot 503 \times 1 \cdot 75}{\cdot 0055} = 160.$$

Now allowing, say, 3,000 ampere turns for p_2 as a preliminary step, we get P = 15,000—that is, 7,500 on each limb, whence the length of winding is $\frac{7500}{7 \times 160} = 6 \cdot 7$in., say, 7¼in. outside measurement of the case. Setting these dimensions

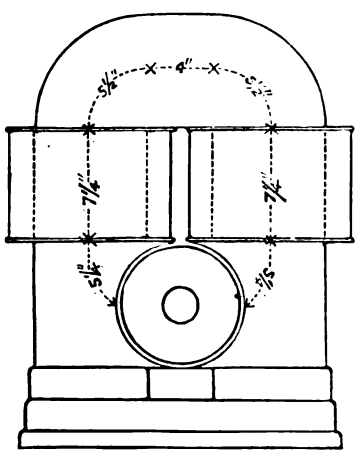

Fig. 15. (One-twelfth full size.)

out in Fig. 15, the mean length of the external field is seen to be 40in. The resistance R_F is thus $\frac{80}{59 \cdot 5} = 1 \cdot 34$, which, multiplied by the saturation coefficient K_2, is $1 \cdot 34 \times 2 \cdot 45 = 3 \cdot 28$, giving $p_2 = 3 \cdot 28 \times 846 = 2{,}780$, whence P = 14,780.

The weights of iron and copper in this machine are as follows:—

Armature core	80lbs.
„ winding	33 „
Field-magnet cores	630 „
„ winding	140 „

the excess over the weight of the ring machine being

Iron	105lbs.
Copper	73 „

On comparison this excess weight is seen to be almost entirely in the field-magnets, and is due to the fact that the nature of drum armatures is such as to offer a large iron section for the passage of the magnetic lines, and to afford comparatively little space for the copper winding; hence the field-magnets must be large in proportion. The weight of the whole is also increased by the use of a smaller heating coefficient ρ in designing the armature.

The electrical resistance of the armature is ·0227 ohm, and the loss in watts $\cdot 0227 \times 10{,}000 = 227$. In the field-magnets the loss is 435 watts. The electrical efficiency is thus $\frac{10000}{10000 + 435 + 227} = 94$ per cent., 1 per cent. higher than in the ring machine.

(To be continued.)

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XLV.

BY OLIVER HEAVISIDE.

Effect of a single conducting bridge on an isolated wave. Conservation of Current at the bridge. Maximum loss of energy in bridge-coil, with maximum magnetic force. Effect of any number of bridges, and of uniformly distributed leakage. The negative tail. The property of the persistence of momentum.

Let a non-distortional circuit be bridged across anywhere by a wire whose conductance is k, and let us examine its effect on a wave passing along the circuit. In the first place, we may remark that we have already solved one bridge problem, viz., the result due to an impressed force in the bridge itself, this being made a special case of the first part of the last Section, by limiting the number of radial circuits to two of the same type.

Now let V_1, V_2, and V_3 be the potential differences in corresponding parts of an incident, reflected, and transmitted wave; V_1 going from left to right on the left side of the bridge, V_2 from right to left on the same side, and V_3 from left to right on the further side of the bridge. At a certain moment these are coincident, viz. at the bridge itself. Then, by the properties of positive and negative waves and elementary principles, we have the following full connections:—

$$\left.\begin{aligned} &V_1 = LvC_1, \quad V_2 = -LvC_2, \quad V_3 = LvC_3, \\ &V_1 + V_2 = V_3, \quad C_1 + C_2 = C_3 + kV_3. \end{aligned}\right\} \quad . \quad . \quad (46d)$$

From these we find

$$-\frac{V_2}{V_1} = \frac{C_2}{C_1} = \frac{k}{k + 2Sv}; \quad \frac{V_3}{V_1} = \frac{C_3}{C_1} = \frac{2Sv}{k + 2Sv}; \quad . \quad (47d)$$

Particularly notice that

$$C_1 = C_2 + C_3, \quad . \quad . \quad . \quad . \quad . \quad (48d)$$

which, though extremely simple, is not by any means obvious at first sight, whilst it is an extremely important property. It is an example of the persistence of momentum; though this may not be immediately recognised, it will be made plain enough later on.

These equations should be compared with (36*d*), (37*d*), the corresponding ones relating to the effect of a resistance r inserted in the circuit. We see that this resistance is replaced by the conductance of the bridge, that L becomes S, and that V and C change places in the expressions for the ratios of the transmitted and reflected waves to the incident.

If we fix our attention upon the current, we see that every element of current, when it arrives at the bridge, is split into two, in the ratio of k to $2Sv$, or of $\frac{1}{2}Lv$ to k^{-1}, half the critical resistance to the resistance of the bridge. The first part is reflected, increasing the current on the left side, and lowering the potential-difference; whilst the other part is transmitted. The electrification in the reflected wave is negative, if that in the incident wave be positive; and conversely.

It may be as well here to remind the reader that from left to right is the arbitrarily assumed positive direction in the circuit, which is the direction of motion of a positive wave (therefore so-called), whilst a negative wave goes from right to left. Also, that the sign of the current, whether positive or

Digitized by Google

negative, is a quite different thing. That is, the current in a positive wave may be negative, and the current in a negative wave may be positive, or the reverse. What is a possible source of some preliminary confusion is the fact that the vector we term the current, and the vector direction of motion of a wave, are in the same straight line, one way or the other. These connections are all summed up in $V_1 = Lv C_1$, the property of a positive, and $V_2 = -LvC_2$, the property of a negative wave. If the first of these relations be true, the wave must move from left to right, whether V and C be both positive or both negative; whilst if the second be true, the wave must move from right to left. I can also recommend the reader to take the advice before given to fix his attention upon the electromagnetic field which is implied by a stated V and a stated C, viz.: a field of electric displacement across the dielectric from one conductor to the other, and a field of magnetic induction round the conductors. A very useful purpose may perhaps be served by a careful study of the properties of the non-distortional circuit, viz.: to assist in abolishing the time-honoured but (in my opinion) essentially vicious practice of associating the electric current in a wire with the motion through the wire of a hypothetical *quasi*-substance, which is a pure invention that may be well dispensed with.

Returning to the effect of a bridge, notice that by the union of (48*d*) with the last of (46*d*), we produce

$$2C_2 = kV_3. \quad . \quad . \quad . \quad . \quad . \quad (49d)$$

That is, the current in the bridge equals twice the current in the reflected wave. The corresponding property when it is a resistance r inserted in the circuit that is in question is, by (36*d*), (37*d*),

$$2V_2 = rC_3; \quad . \quad . \quad . \quad . \quad . \quad (50d)$$

that is, the fall of potential through the resistance equals twice the difference of potential of the reflected wave.

If the bridge have no resistance, making a short-circuit (subject to reservations that need not be repeated), there is no transmitted wave. In fact, the case becomes identical with that of a terminal short-circuit, producing total reflection with reversal of electrification. If, on the other hand, the bridge have no conductance, it does nothing. If the conductance of the bridge be $2Sv$, or its resistance be $\frac{1}{2}Lv$, the transmitted wave is half the incident, or the attenuation due to the bridge is $\frac{1}{2}$. Then, by superimposition, the current on the left side is increased in the ratio 2 to 3, and is therefore made three times the transmitted current.

The current in the bridge being kV_3, and the corresponding heat per second divided by v being the heat due to the bridge per unit length of the incident wave, this amounts to

$$kV_3^2/v = 4S^2V_1^2kv/(k+2Sv)^2, \quad . \quad . \quad (51d)$$

by (47*d*). If k be variable, we make the quantity in question a maximum when $k = 2Sv$, which is the above case of attenuation $\frac{1}{2}$. The heat in the bridge per unit length of the incident wave is then $\frac{1}{2}SV_1^2$, which is half its energy; the other half is equally divided between the transmitted and reflected waves.

If this bridge-wire be a coil of a given size and shape, the variation of k implies a variation of the thickness of the wire and of the number of turns. So that, in a well-known manner, the magnetic force of the coil varies as the current in it and as the square root of its resistance; in another form, the square of the magnetic force varies as the product of the resistance of the coil into the square of the current, that is, as the heat per second. Hence, by what has just been said, the magnetic force is also a maximum when the resistance of the coil is $\frac{1}{2}Lv$. Notice that this is the impedance of the circuit as viewed from the coil itself. A correction is required for the inductance of the coil. It ought not, however, to be a very large correction, if it be a telephone that is in question, and of a really good type, having the smallest possible time-constant consistent with other necessary conditions. We require the magnetic force to be a maximum (*i.e.*, due to the current coming from the circuit) to make the stress-variations the greatest possible, and act most strongly on the disc. [*See* "Theory of Telephone," *Electrician*, February 11, 1887.] Allowing for the inductance of the coil, if the currents be sinusoidal, we require equality of its impedance to that external to it, which is the general law.

Now let there be any number of bridges at different parts of the circuit, and let the ratio V_3/V_1 of a transmitted to an incident wave be denoted by s, its value being given by (47*d*), separately for each bridge. Let also ρ_1, ρ_2, etc, be the attenuations due to the circuit in the different sections into which it is divided by the bridges, and start with an isolated positive wave V_1 at A, the beginning of the first section. On arrival at the first bridge, it has attenuated to $V_1\rho_1$. What passes the bridge (not what crosses it) is $V_1\rho_1 s_1$, which attenuates to $V_1\rho_1\rho_2 s_1$ on arrival at the second bridge. Then there is another sudden attenuation, to $V_1\rho_1\rho_2 s_1 s_2$, followed by a gradual attenuation in the third section, to $V_1\rho_1\rho_2\rho_3 s_1 s_2$; and so on, to the end of the circuit, at B. The disturbance is then attenuated to $V_1\rho s_1 s_2 \ldots s_n$; where ρ is the product of all the former ρ's, or the attenuation due to the circuit from A to B, and s_n is the last s, belonging to the bridge next to B. If the absorbing resistance Lv be put at B, it will at once absorb the wave just described; but after that there will come dribbling in and be absorbed the dregs of the original disturbance at A, arising from the complex system of small reflected waves due to the bridges across the circuit, much attenuated by the many to and fro journeys. But if there be but one bridge, and the absorbing resistance be put at A, to get rid of the wave reflected from the bridge, then there is no dribbling in at B.

However many bridges there be, there is, by (48*d*), no attenuation of current due to them, when its integral amount is considered, but only a redistribution of current. This exactly corresponds to the absence of any alteration of the total charge by inserting resistances in the circuit. They merely redistribute the charge.

If there be n bridges in the distance x, each of conductance k, the total attenuation produced by them is, by (47*d*),

$$s^n = \{1 + k/2Sv\}^{-n}. \quad . \quad . \quad . \quad . \quad (52d)$$

Now place the bridges at equal distances apart, and increase the number n in the distance x indefinitely, keeping the total conductance constant, $= K_1x$, say. In the limit we shall arrive at a uniform distribution of leakage, K_1 being its conductance per unit length, and the attenuation due to it will be the limit of

$$\{1 + K_1x/2Svn\}^{-n}, \text{ with } n = \infty,$$
$$= \epsilon^{-K_1x/2Sv}. \quad . \quad . \quad . \quad . \quad (53d)$$

This is therefore the attenuation of the nucleus, when an initially isolated disturbance travels through the distance x, due to the extra leakage K_1 per unit length. There is, in addition, the regular attenuation due to the circuit. Disregard this for the present, by letting the circuit have no resistance and no leakage, that is, no leakage before the leakage represented by K_1 was introduced. Then we see that if there be initially an isolated disturbance represented by $V_0 = Lv C_0$, extending through the very small distance a, it becomes, at the time x/v later, removed a distance x to the right, attenuated to (writing K for the leakage conductance per unit length)

$$V = LvC = V_0\epsilon^{-Kx/2Sv}, \quad . \quad . \quad . \quad . \quad (54d)$$

extending through the distance a, with a tail of length $2x$ behind it. This tail is of the negative kind, the electrification being opposite in kind to that in the head, and is such that the line-integral of the current in it amounts to

$$C_0a(1 - \epsilon^{-Kx/2Sv}), \quad . \quad . \quad . \quad . \quad . \quad (55d)$$

because this, when added to the corresponding line-integral for the head, according to (54*d*), makes up C_0a, the initial value of the line-integral.

This tail is, as regards current, of the same shape as the corresponding tail due to resistance, as regards electrification, so its equation may be derived from (45*d*). But I shall consider the tails all together in a later section.

The property involved in (48*d*), which leads to the deduction of (55*d*) from (54*d*), is worthy of notice. It is the persistence (or conservation) of momentum. If a circuit have no resistance, then, as Maxwell showed, we cannot change its momentum, the amount of induction passing through it. This was a linear circuit, with the current of the same strength all round it. Now our example is a remarkable extension of this property. Our circuit is linear and of no resistance, but it has any number of leaks, or conducting bridges, as well as

Digitized by Google

what is equivalent to a series of condensers. The current in the circuit may be varied indefinitely in its distribution, but we cannot change its momentum. The line-integral of LC expresses the momentum, but since L is here a constant, of course the line-integral of C cannot change either. This property only continues true so long as there is no resistance bounding the magnetic field; therefore, if the circuit be of finite length, we must not insert resistances at the terminals. For instance, short-circuit at A and B, and we can at once say what will ultimately happen due to any initial distribution of current. It will settle down to uniformity of distribution, *i.e.* making a uniform magnetic field, so that the strength of current will equal the original total momentum divided by the total inductance. There is of course a loss of energy in the settling down, due to the leakage. If the circuit be infinitely long, so that the disturbance can spread out indefinitely, the total energy will decrease asymptotically to zero, in spite of the persistence of the momentum, which indeed tends to zero in any finite length, but keeps its total amount unchanged.

If the circuit have resistance, the *total* momentum decreases according to the time-factor $\epsilon^{-Rt/L}$, whatever be the initial distribution, if it be short-circuited at A and B, or be infinitely long. On the other hand the total charge subsides according to the time-factor $\epsilon^{-Kt/S}$, if the circuit be *insulated* at A and B, or else be infinitely long. The meaning of terminal short-circuit or of insulation may clearly be extended to various other cases not involving loss of charge in the latter case (*e.g.* a terminal condenser) or of momentum in the former, with appropriate corresponding changes in the measure of S or L respectively.

(To be continued.)

THE WESTINGHOUSE TRANSFORMERS.*

It is well known that, in order to avoid heating and consequent waste in electric transformers, the iron must be ample in section and well laminated. It has also been found that the best results are obtained when the coils are entirely surrounded by iron.

In order to make the construction of such coils convenient, Mr. Albert Schmid, of the Westinghouse Electric Company, has designed a form of core which consists of thin plates, each in one piece, which completely surround the coils. The transformer, as it appears with the outer casing removed, is shown in Figs. 1 and 2,

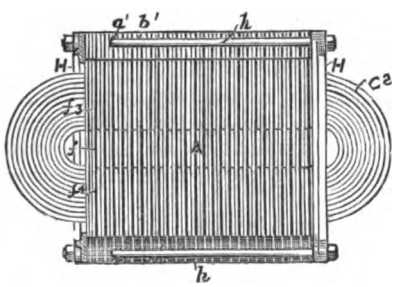

FIG. 1.

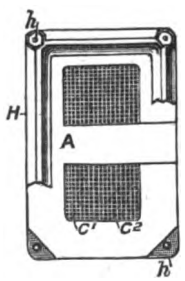

FIG. 2.

and the manner in which it is built up is shown in Figs. 3 and 4. As will be seen, the primary and secondary coils C^1 and C^2 are surrounded by an iron core A, which is composed of thin iron sheets or plates a^1, alternate ones of which are magnetically separated from each other by thin sheets b^1 of paper pasted to the plates of iron.

In preparing the plates a^1, rectangular sheets are stamped with two holes e^1 e^2, which are themselves rectangular in form, and of such size as to receive the primary and secondary coils. Each opening e^1 and e^2 is cut open, as shown at f^1 and f^2, respectively, the cuts being in a line with the inner edges of the corresponding openings. It is not always found necessary to have the cuts exactly in line with these edges; but one or both of them may be in a diagonal direction, as indicated by the dotted lines in Fig. 3. This has the advantage of sharpening the tongue f and making it more easy to insert it in the coils.

The central tongue f extends through the interior of the coils. The separate plates are then applied by springing the portions f^3 and f^4 backward, in the manner shown in Fig. 3, then thrusting the tongue f through the coils and allowing the plate to return to its normal, Fig. 4. The iron used is so thin that the operation may be very readily performed by hand without the use of machinery.

For the purpose of breaking joints the alternate plates a^1 are inserted from opposite side, so that the slits f^1 f^2 of one plate are against the solid portions of the two adjacent plates. The plates are so placed that the bare metallic surfaces of two plates rest against each other, and the opposite insulated surfaces of these plates rest against corresponding insulated surfaces of their contiguous plates.

In building the converter, the plates are temporarily pressed together by clamps. The plates, when as many as practicable have been inserted, are tightly pressed against each other, and to accomplish this two end plates, H and H, are placed at the ends of the converter and bound against the same by four bolts, h, h, h, and h. The plates H and H are of cast iron, surrounding the projecting ends of the coils and resting against the edges of the end plates a^1. To render the completed converter as compact as possible the corners of the plates are cut off to allow room for the bolts.

In running the circuits for distributing the currents by means of converters, the method pursued in a number of instances consists in extending the primary conductors along one set of cross arms of a line of poles, the upper arms, and the secondary conductors along the lower arms. The converters are mounted upon the poles at convenient distances, the primary coils being connected in circuit with the primary conductors, while the secondary coils have their terminals connected with the secondary conductors. The feeders are led from the secondary conductors at the desired

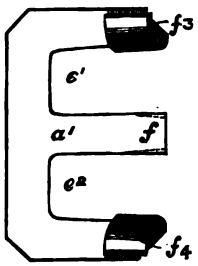

FIG. 3.

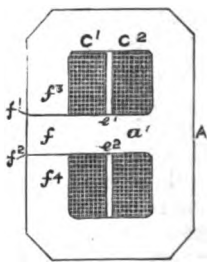

FIG. 4.

points, and the converters are inserted wherever required for maintaining a constant difference of potential throughout the secondary circuit.

BRITISH ASSOCIATION, 1886.

The following paper, amongst others, was contributed to the last meeting of this Association on various subjects connected with Electrolysis:—

RECHERCHES SUR LA CONDUCTIBILITE GALVANIQUE DES ELECTROLYTES.

BY SVANTÉ ARRHENIUS.

Abstract by OLIVER LODGE. *Remarks by Abstracter in square brackets.*

(Concluded from page 324.)

§ 13. Consequences of the variation of the coefficient of activity and of solubility in heterogeneous systems.

The influence of the variation of the coefficient of activity is much greater for heterogeneous systems in equilibrium than for homogeneous ones. The equation (2A) has the form—

$$(1-x)\,a\,.\,c\,\delta = x^2\,\beta\,\gamma,$$

where c is the quantity dissolved of a slightly soluble or gaseous body, $(1-x)$ the quantity of its conjucate body, and x the dissolved quantity of its opposite. The coefficients of activity are δ, α, β, and γ, respectively.

Let us first examine the influence of pressure.

If the body whose mass is c is a solid, one may reckon that pressure affects nothing, and so—

(45) *A system heterogeneous with regard to a solid is independent of pressure.*

This proposition is in full agreement with fact according to the researches of M. Bunsen (Liebig *Ann.*, T. 65, p. 81. 1848).

If, on the other hand, the c body is a gas, c will be approximately proportional to the pressure *of the gas in question* on the surface of the solvent. So if this pressure is zero, $x=0$. This case is realised if one lets the gas escape from the solvent as fast as it is produced. If the pressure increases, c increases also. For this reason the opposite bodies (whose masses are $x\,\beta$ and $x\,\gamma$) will increase, and the conjugate bodies will diminish. Such a phenomenon has been observed in a lot of cases.

If, for instance, one of the opposite bodies is also a gas, as (for instance) when H_2S acts on an alkaline carbonate, one has the equation—

$$(1-x)\,a\,.\,c\,\delta = c'\,\beta\,.\,x\,\gamma]$$

Digitized by Google

By giving to the pressure of H_2S a sensible value, and by separating the carbonic acid which is liberated (*e.g.* by a continual stream of H_2S), one finally arrives at the result that c', and therefore also $1-x$, are zero, *i.e.* that all the carbonate will be transformed into sulphide. *Vice versâ*, by leaving to c' a sensible value, and decreasing c, one could displace the H_2S of an alkaline sulphide by CO_2.

Nevertheless, in the majority of cases the mass of gas dissolved is small in comparison with dissolved other matter. In this case x, that is the quantity of opposite bodies found, will be insignificant, so that the influence of the gas on the system is not notable. Thus, we cannot in general observe changes of equilibrium produced by the presence of gas unless the dissolved quantity of the opposite body is not very small. This case is realised if the body is either gaseous or but slightly soluble, and it has been considered. But also, in the second case, one could perceive the influence of the gas, for the products due to its presence precipitate themselves and disappear from the system. The precipitations of metallic salts by H_2S is a well-known example.

An influence analogous to this of pressure is exerted by temperature if the body with regard to which the system is heterogeneous is solid. The solidity of solids increases with heating. So c and x increase, while $1-x$, the quantity of conjugate body, diminishes. This conclusion has been verified by numerous experiments. One finds many in the works of M. Ostwald, who has studied the phenomena accompanying the solution of some oxalates (CaC_2O_4 or ZnC_2O_4) by an acid. M. Ostwald expresses the said conclusion thus:—

(46) *The influence of temperature on the quantities dissolved by a given acid at constant dilution is always to increase th t quantity.*

Another way of increasing the dissolved quantity c of a slightly soluble body is to increase the volume of the solution (*i.e.*, to add solvent). In this case one increases β and γ also as well as α. At the same time solubility can be diminished by diminution of concentration, as we shall soon see. But in most cases these disturbing influences cannot compensate the increase of c by augment of volume. So—

(47) *An increase of solvent increases the body opposite to, and diminishes the body conjugate to, the solid with regard to which the system is heterogeneous* (if the perturbing influences are not too great).—Ostwald *J. für pract. Chemie* (1881), T. 23, p. 517, and T. 24, p. 486.

[The author then goes on to consider these "perturbing causes." He quotes examples where the solubility of one substance in water has been shown to be increased by the addition of some other salt. He explains this phenomenon on his theory, and holds that the theory of Guldberg and Waage is insufficient to account for it, and, moreover, that it is not in agreement with the numerical results of Ostwald.]

§ 14. Action between Liquids and Solids.

[The author claims even for solids a certain electrolytic conductivity, and hence a certain, though very small, coefficient of activity. It is thus necessary for completeness to consider the action between liquids and insoluble solids. But inasmuch as the activity of even a trace dissolved is much greater, because spread all through a liquid, than the action of a limited area of surface can be, he says the latter may be safely neglected, and states the law.]

(48) *If a system is heterogeneous with respect to a solid body of which, nevertheless, a very small part is dissolved in the surrounding liquid, one can neglect the reactions which occur at the surfaces of contact between liquid and solid.*

§ 15. Velocity of the reactions.

[In accordance with a previous section the velocity with which $I_1 J_1$ and $I_2 J_2$ form (or with which $I_1 J_2$ and $I_2 J_1$ are destroyed), *i.e.*, the velocity of the reaction is—

$$K\,(q\beta \,.\, p\gamma - m\alpha \,.\, n\delta).$$

The author applies this to etherifications, where the water, alcohol, and ether have insignificant coefficients, the acid being the only active body. In this case the velocity is proportional to $\beta\gamma$, and so simply to the activity of the acid used, being quicker with HNO_3 than HA.]

§ 16. Calculation of numerical examples.

The coefficients of activity being not quite constant according to the first part, slightly different numbers must be used for higher concentrations.

§ 17. Conservation of the type, and predisposing affinities.

[Remarks on reactions among non-electrolytes, and on the behaviour of K_4FeCy_6 with reference to Berthelot's hypothesis on "conservation of type" and "predisposing affinities."]

§ 18. Molten electrolytes

should behave just like others.

§ 19. Cases to which Berthollet's laws are not applicable.

M. Berthelot cites some of these cases. They can be put under two general heads. Either a feeble hydrate is unable to displace a stronger hydrate, although one of the products of displacement is but slightly soluble, or a volatile acid (HCl and HNO_3) partially displaces another acid (H_2SO_4), although this acid is not volatile.

The first case is represented by the formula—

$$(1-x)^2\,\alpha\,\delta = x^2\,\beta\,\gamma < c^2\,\beta\,\gamma,$$

where the feeble hydrate and the salt of the strong hydrate are present in equivalent quantites (originally 1), and where c is the soluble quantity of the slightly soluble substance. x is the quantity of this substance formed, but as x is less than c none is precipitated.

One may write the inequality *a fortiori*,—

$$(1-c)^2\,\alpha\,\delta < c^2\beta\,\gamma,$$

or—

$$\frac{c}{1-c} > \sqrt{\frac{\alpha\,\delta}{\beta\,\gamma}}.$$

So if this inequality is satisfied there is no precipitate. α belongs to the feeble hydrate, β to the strong, δ to the salt of the latter, γ to the salt of the former (the slightly soluble substance); $\alpha\,\delta/\beta\,\gamma$ is in general pretty small, so c may be very small and yet no precipitation occur.

As to the second case, no HCl escapes, and so the system is really homogeneous, and a straighforward partition occurs.

We believe we have proved that objections made to the theory of Berthollet are avoided by the theory here presented.

§ 20. Production of heat in chemical reactions.

As we know, M. Thomsen considers that all bases, if they exist in the form of dissolved hydrates, generate the same quantity of heat when dissolved in the same quantity of an acid. This he calls "saline thermo-neutrality." On the other hand, all acids do not generate the same heat when united to a given base—a circumstance which has appeared very odd to thermo-chemists. After what we have just said, however, it appears to me possible to explain it. It is evident that the thermo-chemical parity between the two hydrates cannot obtain unless both are in the active state. In the inactive state analogous compounds do not play the rôle of hydrates (acids or bases), since they cannot unite to a hydrate of any other nature (of contrary sign) and form water and salt. So instead of supposing, as M. Thomsen does, that the hydrates are in a "forme dissoute," we suppose them to be in the active state. After that we put forth the following very natural hypothesis:—

The chemical process, by reason of which a system of one equivalent acid (active) and one equivalent of base (also active), transforms itself into a new system consisting of a salt (not complex) and water, is accompanied by the same heat production independent of the nature of the acid or base.

The different processes which go on during the neutralization of an acid or a base (both supposed partially inactive) are the following:—

1. Neutralisation of the active parts.
2. Transformation of inactive parts into active ones.
3. Neutralisation of these new active parts.
4. Formation of molecular complexes of the salt produced.
5. Possible solidification of the salt.

Between these five processes it is the sum of the heats produced in 1 and 3 per equivalent of salt formed which ought to be constant, according to the above hypothesis.

The existence of the processes 2, 4, and 5 explains how it happens that the actual heat production can be different in different cases.

[Omitting 5, and considering 4 as small, the author points out that No. 2 process is of least importance for strong acids and bases, and accordingly that for these the heat production may really be nearly constant. But for weak acids and bases a good deal of heat is consumed in the No. 2 process. For remember that "strong" means, in his view, "having a high percentage of active molecules," and "weak" means "having very few active molecules." Moreover, since a molecule's activity is allied with, or equivalent to, its dissociation, it is very natural that its production should be a heat-consuming process. Slight residual differences he explains by No. 4 process, considering sulphates and acetates as more complex than chlorides, nitrates, &c., and makes the following statement:—]

(51) *Increase of complexity is accompanied by production of heat.*

(52) *Transformation from the inactive to the active state is accompanied by absorption of heat.*

(53) *During neutralisation a feeble acid or base generates in general less heat on the whole than a strong one.*

Since now for salts it happens that the activity is smaller as the complexity is greater (see § 2), and the formation of molecular complexes is (by 50) followed by a generation of heat, it is necessary that for salts also the transformation from inactive to active state shall be accompanied by heat absorption. But, by prop. 33, bodies endowed with the smallest activity have the greatest chance of being formed. Thus it follows that—

(54) *In chemical reactions among electrolytes those bodies are* in general *formed in greatest quantity, the formation of which is accompanied by the greatest heat production.*

This is the "principle of maximum work," modified. It is valid *in general*, not always.

[Neglecting now the above process 4, the author points out that process 2 has two parts, one concerned with the acid only, the other with the base only. Call these 2_A and 2_B. Process 1 and 3 he considers all along as giving a constant thermal effect; and so he splits up the total heat production H by all the processes thus—

$$H - h_5 = (h_1 + h_3) + h_{2a} + h_{2b},$$

and states—]

(55) *The heat produced by the neutralisation of an acid A by a base B (less heat if possible solidification) is equal to a constant,* plus *a term depending on the nature of the acid only,* plus *another depending only on the nature of the base.*

This has been verified by the experiment of M. Thomsen. A table of the heats of formation of some salts from the results of Berthelot and Thomsen are given. It is on such numbers as these that the rule of Thomsen is founded.

§ 21. Heat of Activity.

This is the name given to the heat used in transforming a body from inactive to active state.

Now, if an acid unites with a base one can regard the process as the displacement of a feeble acid (water) from its salt (basic hydrate) by a stronger acid. Then, if every substance concerned were perfectly active, the heat of neutralisation of water ought to be the same as that of the strong acid, according to the hypothesis at the beginning of last section, and so no heat production should result from the interchange. But if the water, as fast as formed, passes into an inactive state, its heat of activity will be set free. In fact, it is necessary to suppose that water, immediately after its formation, is perfectly active, for it is formed by the collision of two ions H and OH, endowed with movement. But this activity is instantly lost, and almost inactive ordinary water results. Thus we have shown that—

(56) *The heat of neutralisation, set free by the transformation of a perfectly active base, and acid into water and simple salt, is only the heat of activity of the water.*

One might call this *the thermoneutrality of perfectly active electrolytes.* It is intimately connected with the Williamson and Clausius hypothesis. For as it is reckoned, by this hypothesis, a fair chance whether an iron encounters a similar or a dissimilar one, no work can be done by mere interchanges of ions.

Inactivity of salts is founded on complexity, and to make them more active one must split up molecular complexes. Inactivity of hydrates is caused by more or less disaggregating the molecule into its ions. Either process consumes energy. Elevation of temperature partly effects the process and does the necessary work in liquids, though not in solids, for solids have no appreciable activity even when warm. So it is natural to expect that the specific heat of a substance in the liquid state should be decidedly greater than in the solid state, at least for electrolytes.

For elements and non-electrolytes one would expect the difference to be less marked.

Table of atomic heats in liquid and solid states to confirm this :—

Atomic Heats.

—	Solid	Liquid	—	Solid	Liquid
Bromine	13·3	18·1	Tin	6·5	7·5
Iodine	13·7	27·5	Bismuth.....	6·4	7·5
Phosphorus	11·8	12·7	Water.....	9·0	18·1
Sulphur	12 8	15·0	KNO_3.....	24·2	33·5
Mercury	6·4	6·7	$NaNO_3$	23·7	35·9
Gallium	5·5	5·6	$CaCl_2$	37·6	60·1
Lead	6·5	8·3	Phosphate of Soda	14·7	26·7

(The iodine figure seems to need revising.)

Again, when a body melts, if an electrolyte, it becomes partly active, and extra energy is thus required than if it were non-electrolytic ; so we may expect the latent heat of fusion to be in general higher for electrolytes than for elements.

[Table of latent heats of fusion to show this follows, but the difference is not exceedingly well marked, and there are exceptions.]

Most chemists are inclined to imagine a force between different bodies called that of affinity.

On this view the heat produced by chemical processes is the transformation of a potential energy into heat energy. Berthollet, who adheres to such an opinion, was thus conducted to the necessary consequence that chemical compounds have not a constant composition—a result generally admitted to be erroneous (see § 23). Besides, there are other circumstances in favour of the contrary opinion, viz., that the heat produced by chemical processes is analogous to latent heat. Thus, nobody can deny the complete analogy between dissociation (*e.g.* of $CaCO_3$) and the vaporisation of a liquid, after the researches of Deville, Debray, Troost, Isambert, Ditte, Naumann, and others of the same school.

But the above-given theory conducts of necessity to the latter opinion. So it is from this point of view also in agreement with experimental fact.

§ 22. Comparison between some found and calculated numbers.

M. Ostwald has drawn up a table of the values of the coefficients of relative affinity for different acids, taking that of HNO_3 as 1. The definition given by Ostwald of this coefficient coincides perfectly with that of "avidity," given by Thomsen, who has likewise given a table. We reproduce below both these tables together. . . . . Sulphuric and oxalic acids are liable to form double salts which complicate matters a little (§ 10), but at extreme dilution not much, so their numbers vary with concentration (see § 12).

The coefficients quoted are, for want of better, those applicable when no other body is present; but other bodies, if present, diminish them, just as concentration of the same body does. And feeble hydrates which are most affected by concentration are probably most affected by foreign bodies. These feeble hydrates, therefore, may be expected to be really a little weaker than calculation shows.

The determination of avidity has been made by permitting an equivalent of each to share an equivalent of base (usually NaOH) between them ; the rate of the fractions of the base seized by each acid is their relative avidity. Two numbers are calculated for H_2SO_4, one if it does not, the other if it does, form an acid salt. As for phosphoric acid, we have supposed that its acid salt has only one H replaced by a metal—a supposition which ought not to be pressed, seeing the great excess of free acid present in a reaction. The following are the only acids for which there are data enough to calculate from. The base supposed in the calculation is NaHO for HNO_3, HCl, HI and HA, for the others KHO.

The formula used is that of § 10—

$$(1-x)\,(1-n\,x)\,\alpha\,\delta = x^2\,\beta\gamma,$$

where $n=1$, except for H_2SO_4, when $n=2$, and for H_3PO_4, when $n=3$. The following table gives the results :—

Relative Avidity of Acids.

——	Ostwald exp.	Thomsen exp.	Arrhenius calculation.
HNO_3	100	100	100
HCl	98	100	92
HBr	—	89	86
HI	—	79	92
H_2SO_4	50 to 90	49	47 6 to 85
H_3PO_4	—	13	21·7
$C_2H_4O_2$	1·23	3	8·2

Ostwald specially says that his numbers involve considerable uncertainties, so the agreement is sufficient.

§ 23. Review of anterior theories.

Finally the author reviews the theories of Berthollet, Berthelot, and Guldberg and Waage. He points out that many objections to views expressed in Berthollet's essay of 1803 are met and removed by his own theory. He regards these views as true, but as requiring amplification and additional statements which he supplies.

As to Guldberg and Waage, he says their theory develops itself slowly from 1864 to 1879 in three distinct stages. In the first two memoirs they postulate "forces of action" acting between substances, and in the firs. they give the equation—

$$a\,(p-x)^a\,(q-x)^b = a_1\,(p_1+x)^{a_1}\,(q_1+x)^{b_1},$$

where the indices may be quite different ; and they oppose the view of Berthollet that affinity is proportional to mass.

But in this second memoir they put all the indices = 1, and so abandon this ground. But they still continue the hypothetical "forces of action." Arrhenius objects to these forces as incalculable and unnecessary.

In their third memoir G. and W. introduce the idea of a portion only of each body taking part in the reaction, and think of the number of encounters between such active molecules, and so of the velocity of the reaction, as proportioned to their product, much the same as Arrhenius does.

For heterogeneous systems G. and W. think the surface of the solid present exerts an influence ; but A. says it cannot, or it would vary with the extent of surface, which it does not. In § 13, he says, is cited an experiment fatal to the theory of Guldberg and Waage, according to M. Ostwald, but not inexplicable by the new theory.

Résumé.

"In the present part of this work we have first shown the probability that electrolytes can assume two different forms, one active, the other inactive, such that the active part is always in the same exterior circumstances (temperature and dilution) a certain fraction of the total quantity of the electrolyte. The active part conducts electricity, and is in reality the electrolyte ; not so the inactive part. Moreover, we have proved that the necessary consequence of the hypothesis of Clausius and Williamson is that there exist circular continuous currents. In these currents the active parts alone participate.

"The molecules participating in such currents are necessarily decomposed, according to the scheme of double decomposition, and the result is that new electrolytes are formed. On this basis we have built a chemical theory of electrolytes which, deduced from very probable sources, possesses also a high degree of probability. This theory leads to formulæ applicable to chemical processes, formulæ very conformable to those proposed by MM. Guldberg and Waage,* which have been verified by a great number of experiments. We have also pointed out that the results of this theory agree very accurately with the opinions of Berthollet.

"As a provisional hypothesis we have supposed the coefficient of activity equal to the molecular conductivity. The figures calculated on this supposition, and the reactions thus foreseen, agree very well with experimental facts. We have also from this theory deduced a number of electro-

* The probability of the correctness of the theory is increased to a high degree by the fact that in deducing the formulæ given above we ignored completely those of MM. Guldberg and Waage, formulæ of whose existence we had no knowledge before obtaining the work of M. Lothar Meyer (which only happened after the greatest part of this memoir had already been written). Thus we have found these formulæ without any occasion to construct them in some preconceived manner, and guided solely by the theory of Clausius and Williamson, and by the notion of an active and an inactive state of electrolytes. [Author's note.]

Digitized by Google

chemical laws, among others the laws of Faraday and Hittorf; as well as, by the aid of the hypothesis, that every electrolyte has a constant composition we have proved the necessity for the existence of equivalent weights of every substance playing the part of an ion (law of Richter). From data on the variations of conductivity and of solubility we have indicated the reason of a number of phenomena which are set up in equilibrating systems, by dilution, by heating, and by addition of foreign bodies. Finally we have, by aid of an hypothesis very probable in the present state of thermo-chemistry, deduced the principal propositions of thermo-chemistry (among others the "principle of maximum work"), propositions which, however, by reason of the mode of their deduction, are not valid in every case, but only "in general." Also we have indicated the nature of chemical energy, as analogous to that of latent heat; an indication with which specific heats, latent heats, and the phenomena of dissociation correspond.

"All these propositions and all these laws are taken from the most different departments of chemical science; but as the theory agrees so well with reality in these different points, it seems probable that it ought to do so also in intermediate regions. Moreover, we have tried to prove that the differences between this theory and that which, after the examination of M. Lothar Meyer, is now the most probable, relate to opinions of the authors of the said theory, which to a deeper examination show themselves unsustainable either from the theoretical or the experimental point of view. We have thus approached more nearly the theory of Berthollet than MM. Guldberg and Waage have done. And this circumstance speaks, we believe, in favour of the above-developed theory. But here are reasons of greater importance. The theory of Guldberg and Waage (still less any other theory) cannot in its present state deduce more than a fraction of the propositions and laws given above. The constants necessary for the prevision of reactions can, according to the new theory, be approximately deduced from other constants known in other branches of science. Some of the propositions given above, and agreeing with fact, are contrary to the theories of MM. Guldberg and Waage. The difficulty inherent in every theory of electrolysis, and also in the hypothesis of Clausius and Williamson in its primitive form, is totally removed by the new theory. As, besides, the theory given above is founded on very probable bases, and is totally free from every hypothesis of an affinity different from physical forces, it is not doubtful, we think, that this theory will be preferred to all chemical theories hitherto published.

"True, one could object that this theory is only applicable to electrolytes, while previous ones have embraced all substances.

"Against this we remark that chemical knowledge is mainly based on the reaction of electrolytes, which seem in chemistry to play the same rôle as gases do in the mechanical theory of heat. For the rest, the idea of an electrolyte has an extent much greater (according to the law of Hittorf) than one is accustomed to attribute to it. Thus, reactions in general seem to manifest a considerable analogy to those of electrolytes, so that one could perhaps in the future enlarge the theory given for electrolytes so as to be, with some modification, available for all substances."

THE LIGHTING OF THE BRITISH MUSEUM.

In the House of Commons on Tuesday last, on the vote of £147,385 for the British Museum,

Mr. Molloy said that he regretted that the expectations which had been raised with regard to the lighting of the Museum by electricity and the admission of the public at night during hours which would suit the convenience of the working classes had not been realised.

Sir J. Campbell urged the expediency of lighting by electricity the natural history department at South Kensington.

Colonel Duncan, as representing the district in which the British Museum was situated, supported the proposed improvements on the condition that the staff was correspondingly increased.

Mr. Jackson believed that the proposed alterations would involve a large addition to the staff and a considerable increase of expenditure annually over and above the large expenditure which would have to be incurred at the outset. He had been in communication with the authorities of the Natural History Museum with the view of extending the hours for admission. The question of lighting, however, was a more difficult one, requiring very careful consideration, which it would receive.

Mr. Labouchere suggested that the British Museum should be lighted by electricity or should be opened on Sundays.

Sir R. Fowler would oppose Sunday opening of the Museum, but thought that the question of lighting the building in the evening was worthy of consideration.

Mr. W. H. Smith remarked that a reduction of the vote would merely tie the hands of the Government. The question deserved serious consideration, and if the hon. member would be content with the discussion, he would undertake that there should be a careful examination of the facts during the recess. The Government would endeavour to meet the views of Parliament and of the metropolis. There was, however, great responsibility, both as regarded the Exchequer and as regarded the valuable collection in the hands of the trustees.

THE LANCASHIRE AND CHESHIRE TELEPHONE EXCHANGE COMPANY.

Report of the directors for the year ended June 30, 1887, to be presented to the shareholders at the sixth ordinary general meeting of the Company, to be held on Monday, the 29th inst., at half-past 11, at the Memorial Hall, Albert-square, Manchester:—

The subscriptions and rentals (including those of the out-districts) pertaining to the financial year, amount to £82,490. 14s. 6½d. as compared with £72,508. 13s. 2d. for the year ended June 30, 1886. The amount of income carried forward to next year's revenue, as representing sums received in advance for periods extending beyond 30th June, 1887, is £38,276. 17s. 4d., against £34,681. 1s. 8d. in previous year's balance-sheet. On the past year's working the profit is £28,049. 19s. 3d. After deducting from this sum bank interest, interest on reserve fund, and the interim dividend paid in February last, there remains a balance of £14,212. 11s. 10d. The Directors now recommend a further dividend at the same rate as in February, making a complete dividend of 7 per cent. for the year ended 30th June, 1887. After providing for this dividend

ELECTRICAL TENDERS AT CHICAGO.

The following is a list of the tenders received for the lighting of the river banks and bridges at Chicago. Some account of the character of the work was given in this journal on page 283, and it will perhaps be remembered that about ten miles of cable are to be laid under water. The competition has evidently been very severe, but owing largely, no doubt, to the careful specification drawn by Prof. Barrett, the city electrician, the prices are fairly well together.

	Electric and steam plant.	Cables.	Guaranteed coal consumption per H.-P. per hour.	Amperes.	Volts.	Circuit tension.	Electric plant.	Total cost with 10 miles circuit.

Digitized by Google

there will remain, at the credit of profit and loss account, a balance of £1,656. 14s. 1d., which it is proposed to carry forward. A dispute having arisen with the United Telephone Company (Limited), in which judgment, now the subject of appeal, was given against this Company, the Directors do not propose to add to the reserve fund (which, including interest, now amounts to £5,400), but to keep the balance of £1,656. 14s. 1d. in hand. The claim in question arises from a difference in the interpretation of a supplemental royalty agreement, and will in any case involve no loss beyond law expense and interest, as the accrued royalty is already provided for in the accounts. The total number of subscribers, on 30th June, 1886, to the various "exchanges" was 3,483, and of private renters, 1,243; this year, at the corresponding period, the figures were 3,788 and 1,347 respectively. The "exchange" and private line orders on the books at 30th June, 1886, and including work not finished, represented a gross income of £76,115. 14s. 8d. On 30th June, 1887, the amount stood at £81,660. 6s. 4d. showing an increase of new business in these two sections to the extent of £5,544. 11s. 8d., exclusive of the trunk-wire and call-office departments, the gross revenue from which is now at rate of £6,500 per annum—an increase at rate of £1,500 a year since last report. In last report it was announced that your Directors were negotiating with a view to the introduction of a new switching apparatus in Manchester, similar to the one which has answered so satisfactorily in Liverpool. These negotiations are now so advanced that the new board will shortly be brought into operation. Advantage is being taken of this opportunity to concentrate into one switch room all the telephone wires at present dispersed over three separate switch rooms in different parts of the city. The retiring directors are Messrs. Robertson and Thompson, who are eligible for re-election. The accounts have been audited by Mr. C. R. Trevor (Messrs. Trevor and Pilling, Manchester), on behalf of this Company, and by Mr. R. S. Blease (Messrs. Blease and Sons, Liverpool), on behalf of the United Telephone Company (Limited). The Company's auditor, Mr. C. R. Trevor, retires, but offers himself for re-election, for which he is eligible.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 12th and 19th inst. amounted to £3,490 and £2,917 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the two weeks ended August 19th, amounted to £2,950, and £1,614 respectively, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NOTES.

SOUTH AMERICA. — The cable between Chorillos and Mollendo which was broken about a fortnight ago is now repaired.

ALDERNEY.—Direct cable communication between Guernsey and Alderney, which has been interrupted since December last, is now restored.

MONTREAL.—A company is being formed in this city with a large capital for the purpose of providing conduits for the whole of the overhead wires.

CHICAGO.—The contract for the river lighting in this city has been awarded to the Western Electric Company, whose tender amounted to $29,295.

CLUB LIGHTING.—It is stated that during the recess the Carlton Club will be supplied with the apparatus necessary for the purpose of electric lighting. The Athenæum and Junior Carlton are already so lighted.

PONTYPRIDD (WALES).—The guardians of Pontypridd invite tenders for electric bells for the union workhouse. All particulars can be obtained of Messrs. Seward and Thomas, architects, Cardiff. Tenders have to be sent in by the 6th inst.

THE BRITISH MUSEUM.—The electric light is now in operation for the season in the reading room and galleries. The hour of closing is extended to eight o'clock, except for the newspaper room, which will continue to be closed at 6 p.m.

SAN FRANCISCO.—Plans are being prepared for an electric railway about fifteen miles in length in the neighbourhood of San Francisco. The motive power will be obtained from turbines.—A great deal of electric light work is being carried out in California.

CENTRAL AMERICA.—The Central and South American Telegraph Company have obtained concessions from the Columbian Government for a land line to be erected across the isthmus, and for a cable extending from Colon along the Atlantic coast.

PROPOSED UNDERGROUND ELECTRIC RAILWAY.—A company which has just been incorporated in New York proposes to make a tunnel under the East River, to connect Long Island with New York. The tunnel will be five miles in length, and will be worked entirely by electricity.

THE VIENNA OPERA HOUSE.—A fortnight's experience has shown that the electric lighting of the Vienna Opera is a complete success, and, as an evidence of Imperial approbation, Baron Becezny, director of the Imperial Court theatres, has received the Grand Cross of the Francis Joseph Order.

THE AMERICAN CARBON COMBINATION.—It is announced that, owing to the break up of the Cleveland ring, the arc light companies have decided to abandon their intention of forming a mutual carbon manufacturing company. This may be taken as, upon the whole, a satisfactory end of the dispute.

TELEPHONE TENDERS IN SPAIN.—Among the Royal orders published in the *Madrid Gazette* of Friday last, Aug. 26th, are two inviting tenders for the establishment and working of telephones in Granada and in Vigo. Adjudications are to be made on September 27 in the case of Granada, and on September 26 in the case of Vigo.

A NEW SIEMENS MICROPHONE.—Messrs. Siemens Brothers and Co., of Berlin, have brought out (in Germany) a new microphone, in which they have sought to render the surface of contact of the carbons as extensive as possible. Large plates of carbon are employed, and the lower one is suspended by silk threads which pass through a hole in the centre of the plate above.

PITTSBURG.—At Pittsburg there will be in operation very shortly incandescent plant having a total capacity of 53,000 lamps. It is interesting to note that in the boiler rooms the furnaces are heated by natural gas, which by means of regulating valves is completely under the control of the stokers. It is said that if necessary the change from gas to coal can be made in three minutes.

CITY AND GUILDS OF LONDON INSTITUTE.—Some important alterations and additions have been introduced into the programme of Technological Examinations for the year 1887-8. Teachers desiring to form classes should communicate at once with the organising Director of the Institute. A copy of the programme, or 25 copies of any one syllabus, may be obtained by forwarding sevenpence in stamps to the Central Institute, Exhibition-road, London, S.W.

WESTON-SUPER-MARE.—The principal streets of this town were lit by the Thomson-Houston system for the first time on Saturday last. The work has been undertaken through the instrumentality of Mr. Massingham, who, it will be remembered, originated the Taunton Electric Lighting Company. The number of lamps at present in use is twenty-six of 1,200 candle-power; of these, ten are in the streets and the remainder in places of business, hotels, and private residences. There are also upon the same circuit three sets of five incandescents in multiple series.

FATAL ELECTRIC TRAMWAY ACCIDENT AT BLACKPOOL.—On Monday afternoon, as a car of the Blackpool Electric Tramway Company was passing Reid's Baths, a man, apparently about fifty years of age, was observed on the line. The driver shouted to him, but he appeared to become bewildered, and instead of stepping off the line walked in front of the approaching car, which knocked him down, and passed over his legs and the lower part of the body. The driver pulled up, but it was found that the man was quite dead. He proves to have been a Darlington weaver.

SELF AND MUTUAL INDUCTION ON TELEPHONE CIRCUITS.—The *Electrotechnische Zeitschrift* has a paper by J. W. Giltay, in which some experiments upon the effects of self-induction in enfeebling telephonic communication are described. The experiments were more of the nature of demonstrations than of original investigation, and are chiefly devoted to exemplifying the fact that the effects of mutual induction are opposed to those of self-induction because the resultant magnetisation is diminished by the currents due to mutual induction. The practical lesson follows that an electro-magnet in a telephone circuit should either be surrounded by a sheath of copper or should be shunted by a high resistance without self-induction.

AN OIL FILTER.—The Electric Filter Company, of Chicago, have brought out a magnetic filter for cleaning oil which has already been used for lubricating machinery, and enabling it to be used once again. The filter removes the iron particles by means of magnetism. It consists of a vessel contracted in the middle and surrounded at that point by a coil of wire, through which an electric current is caused to circulate. This portion of the cylinder contains iron filings, which are magnetised by the current, and thus attract the iron particles and other metallic particles of magnetic tendency. The oil is further clarified by passing through other filters, such as felt cloths and sawdust, and it is received in a purified condition in the lower receptacle.

ACID-RESISTING CEMENTS.—An American journal gives the following recipes for the composition of two kinds of cement capable of resisting acid, but not having tried either we cannot guarantee their value :—"A cement for resisting sulphuric acid, even at boiling heat, may be made by melting caoutchouc at a gentle heat and adding, with constant stirring, from six to eight per cent. of tallow. Then mix therewith enough dry-slaked lime to make the whole the consistency of soft paste; finally, add thereto about 20 per cent. of red lead, whereby the mass immediately sets hard and dry. A solution of caoutchouc in twice its weight of linseed oil, aided by heating, and the addition of an equal weight of pipe clay, yields a plastic mass which will resist most acids."

THE ELECTRIC LIGHT AT LEAMINGTON.—During the past week a staff of workmen have been employed laying the final length of the electric light cable in Bath-street. The works in Wise-street are now nearly completed, and it is almost certain the light will be turned on to the town during the month of September. It is stated that nearly all the shops on the line of route have applied for the light to be supplied, whilst the Corporation have contracted for lighting the public buildings and lamps at a cost not exceeding that previously paid to the gas company. The contract is terminable at the year end with six months' notice. With the exception of fittings in the Town Hall and pump room, which the Corporation furnish, the undertaking (a costly one) is wholly borne by the company, who have perfect faith in its success.

MINNEAPOLIS.—At Minneapolis they suspend their arc lamps in the street very much after the fashion in which our forefathers hung their lanterns, on a rope stretching across the narrow streets. They erect two tall posts, one on either side of the road, and the lamp is swung from a rope which passes over a pulley at the top of one of the posts, and descends from thence to a small windlass near the ground. By unwinding the rope from the windlass the lamp is lowered. The wires are attached to the post on the opposite side, and are long enough to allow the lamp to reach the ground. This plan was put into operation some time ago by the Minnesota Brush Company, and has proved very successful. Minneapolis also possesses a tower, or mast light, 270ft. in height, and carrying eight lamps of 4,000 candle-power each.

SALZBOURG.—Messrs. Siemens and Halske have nearly completed the extensive installation which they have undertaken for the Municipality of Salzbourg. The price of one lamp-hour of sixteen candles has been fixed at a trifle under 1d. For arc lamps the following tariff is arranged :—

400 to	500	candles,	2·85d. per hour.
600 to	700	,,	4·27d. ,,
800 to	900	,,	5·7d. ,,
1,400 to	1,600	,,	7·13d. ,,

Arc lamps are only supplied in pairs, or a single lamp is charged as for two. Carbons, if furnished by the company, are charged extra ·66d. to 1·4d. per lamp per hour. A further charge is made for the meters, varying from 25s. for ten lamps, or under, up to nearly £4 for installations of fifty to 100 lamps.

SOLDERING TELEGRAPH WIRES.—M. Prisiajirikov, chief of the Posts and Telegraphs in the Government of Samara, Russia, contributes to a Russian periodical with an unpronounceable name (consisting of 58 letters) a practical note on soldering telegraph wires. In order to lessen the time required for the work, and also to avoid the weakening of the wire from scraping the surface, the author has introduced a method which consists of the use of a heating tool, capable of holding a considerable quantity of melted solder, and upon the top of this is thrown sufficient powdered sal ammoniac to leave a layer of liquid salt of some little depth. This liquid is nearly black in colour. The iron wire already covered with binding wire is then pressed underneath the surface of the melted solder passing through the liquid salt. This effects a perfect solder, no matter how dirty the wire may be.

INSULATED RAIL-JOINTS FOR ELECTRIC SIGNALS.—In a communication to the *Railroad Gazette*, Mr. W. G. Blodgett, electrician of the Boston and Albany Railroad, states that the wooden blocks formerly used for insulating the track sections for the automatic electric block signals were abandoned on the Boston and Albany several years since, because they did not keep the rails well in place, and were not durable. Experiments with vulcanised fibre gave but little better results. The method now in use consists in placing behind the fish-plate a strip of "leatheroid" one-eighth of an inch thick, and moulded to fit the rail. The bolts are insulated from the rails by bushings of the same material, and a piece one-quarter of an inch long, of a size and shape corresponding to the cross-section, is placed between the ends of the abutting rails. The fish plates are planed off to allow for the space taken up by the leatheroid strip.

THE LATEST YANKEE "NOTION."—A recent American patent describes a method of working railways by electricity whereby it is unnecessary to make any change in the type of locomotive already in use. This remarkable result is to be attained in a very simple way. The inventor proposes to remove the tender and replace it by a car containing a storage battery and electro-motor of any usual type. The electro-motor is to be employed in compressing air, which is then forced into the boiler and used instead of steam. We are a little surprised to learn that a locomotive built as a steam engine will work quite as well with compressed air; but doubtless that is a point of detail which has been thoroughly considered by Mr. Jeremiah W. Stoker, of Kansas City. We respectfully commend this account to the consideration of *The Times*, which is just now deeply interested in the subject of compressed air.

ELECTRIC TRANSMISSION OF ENERGY IN MINES.—A somewhat remarkable and, so far, successful application of the electric transmission of energy has recently been carried out in a coal mine near Normanton. The motive power required for pumping water to the surface has hitherto been furnished by compressed air; but the engineers in charge were so dissatisfied with the low efficiency obtained—an efficiency not exceeding 25 per cent.—that they determined to try electric power. The pumps are situated at a distance of about 70 yards from the bottom of a shaft, 300 yards in depth; and owing to the damp atmosphere and confined space the conditions were of a peculiarly trying character for electrical machinery. A second pump is now about to be fixed. When the plant has been a little longer at work, and may be presumed to have reached its final stage of development, we hope to give a detailed account of the whole installation, which our readers will probably find to be of considerable interest.

FLAD'S TOWER SYSTEM.—It will be remembered that at New Orleans it was resolved some months ago to make a bold attempt at a solution of the wire difficulty by adopting a proposal of a certain Colonel Flad. The details of this system have now been more fully worked out, and it appears that at every corner (New Orleans being for the greater part laid out on the chess-board plan) will be erected four posts of malleable iron (one at each angle) 150ft. in height, and, according to the *Western Electrician*, only 7½in. in. circumference. The posts

Digitized by Google

run up 40ft. clear of all obstruction, and are then connected by the rods. At the top of the towers will be suspended two steel cables of §in. diameter. Below these, at such a distance as may be required, will be a second pair of steel cables 1in. in thickness, and between these two sets of cables will be strung at intervals of 60ft. "cross-section pieces" of iron or wood, having numerous holes through which the wire will be strung. The contract is now being carried out by the Star Iron Tower Company, of West Wayne, Indiana.

EXTENSION OF LONG-DISTANCE TELEPHONY IN THE MIDLANDS.—Amongst other important extensions of inter-urban telephone lines in the midland counties may be mentioned the following. A trunk line is projected from Nottingham to Derby, thence to Burton-on-Trent and Lichfield, and as a line already exists between Lichfield and Birmingham, this will place Nottingham in communication not only with Birmingham but with the whole of the Black Country district. A second important line is projected from Ilkeston (which is already in connection with Nottingham) to Alfreton, Mansfield, Clay Cross, Chesterfield, and Sheffield. This line will therefore bring the Midlands into direct communication with Yorkshire, and will provide an alternative route to the Lancashire and Cheshire districts. It is further proposed to place the Birmingham centre in direct communication with the Potteries by means of a line from Wolverhampton through Stafford and Stone to Longton, and to provide a second line from Birmingham to Sheffield, *viâ* Hanley, Leek, and Buxton. Lastly, a line is to be built between Nottingham and Leicester.

THUNDERSTORMS. — Heavy thunderstorms were again reported from various parts of the country on Sunday last. Severe thunderstorms raged over the north of Scotland on Tuesday night. At Durness, near Cape Wrath, a house was completely shattered by lightning. The inmates were hurled from the fireside to the door, and were severely injured. On Tuesday, also, at Turriff, Aberdeenshire, Mr. Urquhart, farmer, his son, and two horses, while engaged reaping, were all struck by lightning. On the same evening a severe thunderstorm passed over Buxton. At Dove Holes a house was demolished by lightning, and six persons were struck. One, William Boothby, aged 14, was instantly killed; the others, who were stunned, and lie in a precarious condition, are Mary Ellen Boothby, 20; Joseph Boothby, 13; Sarah Ann Boothby, 10; Joseph Boothby, the father, and his wife. The boy who was killed is badly burned on the body. A man named Lomas, a neighbour, was also stunned. A tall chimney at Bridge Mills, near Warrington, was struck by the lightning, and fell with a crash, doing considerable damage. Damage was also done to the telegraph wires.

ROBERTSON'S WRITING TELEGRAPH.—On Friday, August 26th, the representatives of the press were invited by the Writing Telegraph Company to a private view of this instrument, which has just been brought over from America and is now being shown at a stall in the American Exhibition. The pen of the receiving instrument is attached to an armature capable of motion in the field of a pair of electro-magnets placed at right angles to each other, and the relative strengths of the currents through these coils are varied by the varying pressure excited on two series of carbon discs by a rod, pivoted at its lower extremity, and having its upper end attached to a pen or stylus with which the writing is done. The actual pen of the transmitter is not in mechanical connection with this stylus, but is actuated by it in the same manner as the pen of the receiver. The reproduction is very good, it being almost impossible to distinguish between the slips written at the transmitting and the receiving station respectively. It appears to be a somewhat serious, though apparently unavoidable, drawback to the instrument that it requires a certain amount of practice before it is possible to produce legible writing with it. The instrument is an ingenious one, but is an obvious development of the earlier writing telegraphs of Bakewell and Cowper.

THE MUTHEL DIFFERENTIAL ARC LAMP.—The attempts which have previously been made to construct an arc lamp with two equally inclined carbons have not met with a great deal of success. This principle has, however, such obvious advantages in the way of freedom from shadow and the distance of the arc from the structural supports, that were it not for pure weariness of chronicling the endless modifications of arc lamps, we might be disposed to welcome any renewed attempt giving reasonable promise of success in this direction. The Muthel lamp appears to us to be such an attempt; the principle can be described in very few words. The carbon holders are attached radially to a pair of pinion wheels which gear on either side of the same rack. When the rack descends the carbons are inclined towards one another, when it ascends they are further separated. The pinions are mounted excentrically upon a pair of heavy cams which tend by themselves to bring the carbons together. The rack is fixed at its upper end to an iron core which travels in a double solenoid. The upper half of the solenoid forms a shunt circuit to the lamp, and tends to pull the rack upward, and so bring the carbons together. The lower half of the solenoid is in the direct circuit, and tends to lower the rack and separate the carbons; this is the action which strikes the arc. It is probable that the lamps of this type are better adapted for alternating than for direct currents.

NEW YORK.—During a thunderstorm in New York, one of the arc light circuits on the lower Broadway was struck by lightning and the whole of the lights were extinguished.—The competition for the electric lighting contracts in this city has had the effect of reducing the rate for arc lamps from 70 cents to 25 cents per lamp per night. If the latter is anything like a paying figure—which, however, seems very doubtful—the Brush and the United States Companies, between whom the contract was formerly divided, must have been making a fine thing of it during the last few years.—Not much has been heard of the New York Subway Commission of late; this, perhaps, is in part owing to the fact that its name has been changed to the Board of Electrical Control. The meetings of the Board have recently been the scene of very acrimonious discussions upon the questiom whether, pending the completion of the conduits, the Board should or should not sanction the erection of additional pole lines. One company recently begged permission to erect the modest number of 1,500 poles for electric light cables in the streets. The mayor is vehemently opposed to the erection of any new poles, but for the present he is in a minority on the Board, and in his capacity of chief magistrate of the city he overrules the decisions arrived at by his colleagues. This is all very sad, especially when we remember how kind the Americans were in promising twelve months ago to show us the way to put our wires underground.

ELECTRIC SEARCH LAMP.—During the past week some interesting experiments have been made at Lydd camp with the electric search light. It was desired to work the light under the fire of the rifles and the Gardner guns of an enemy. The engine and apparatus which worked the light were placed under a casemate about 200 yards from where the light was actually seen. The light was so arranged as to be under cover and to throw the rays on to a reflector on the top of a parapet, by means of which the country round was scoured under a

Digitized by Google

shower of bullets fired at it. The reflecting disc had a diameter of 26in., and it was found that although it was struck by bullets several times the damage was practically *nil*, the reflecting power being only diminished by the area of bullet holes. The reflector was worked by four temporary guy ropes, divided equally round its surface, two to give depression or elevation and the other two for lateral direction, all these movements being worked from the casemate. The difficulty in shooting at this bright light was found to be very great indeed. Aim could only be taken through a dark piece of oiled paper placed over the foresight. Ten marksmen of the East Surrey Regiment and a Gardner gun were brought to bear upon the light. Several hundred rounds were fired at 1,000 yards and 600 yards. It was found after two hours' sharp firing that the reflector had been struck fifteen times without being seriously damaged. The light was shown at intervals of about a minute only.

Another "Make and Break" Transmitter. — The American National Telephone Company (one of the opponents of the Bell Company in the States) is exhibiting a transmitter devised by Mr. J. W. Bonta, by which it apparently succeeds in proving conclusively that an undulatory current is not essential for the transmission of speech. The Bonta transmitter consists of a diaphragm which carries a carbon pencil projecting from the centre of its hinder face. The point of this pencil just touches a carbon ball about an inch in diameter, which rests loosely in a groove cut in a brass plate. The plate is tilted towards the diaphragm by an adjustable screw, so that when the ball receives an impulse from the pencil it tends to run up the groove and back again. This transmitter is said to give excellent results. When examined through a magnifying glass the ball is seen in action as if continuously separated from the point. In a series of instantaneous photographs which have been secured the two are shown in all degrees of separation. When a light spring was made to bear upon the ball so as to keep it in contact with the pencil, the transmission of speech ceased. It is argued that these facts prove conclusively that speech is, or may be, transmitted "by the succession of currents of uniform intensity and variable duration, and that their varying duration causes the reproduction of the sound." We should like to know, however, whether the "break" is not usually bridged over by sparking.

Electric Lighting in German Provincial Towns.—A correspondent of *Industries* gives the following particulars respecting some installations in Germany:—"The public supply of electricity from central stations is not limited to Berlin only, but is beginning to obtain a footing in various provincial towns throughout Germany. In Hanover there are two small stations already in activity, one for the supply of private customers and the other for the lighting of the Court Theatre. In this case alternating currents and transformers are used, the transmission being by means of an overhead iron wire 100 mils. in diameter, at a potential of 1,200 volts. The total commercial efficiency of the system is 58 per cent. A larger central station with underground cables for the supply of the inner portions of the town is in contemplation. In Magdeburg there is a small central station for lighting a block of houses, including hotels and shops, in the neighbourhood of the railway station, and in addition to this a separate installation for the theatre is now being fitted up. There will be two gas engines of 35 horse-power each placed in an annexe, and the building will be lighted from the dynamos direct. The works of Gruson and Schäffer and Budenberg in Buckau have also special electric light installations. In Brunswick a private person has erected a central station for 1,000 lamps, all the lights being in a block of houses containing business premises. In Dessau, which is the head-quarters of the Continental Gas Company, there is a very interesting installation which has been at work since last year, lighting principally the Court Theatre and the Castle with about 2,000 lamps. Power is furnished by four Otto gas engines, two of them 60 horse-power, and one 30 horse power, working together on a countershaft, from which two 600-light and one 450 light dynamos are driven. The fourth gas engine is an 8 horse-power working a 100-light dynamo, which is used for charging a battery of Khotinsky accumulators, having a total capacity of 600 lamp hours. The cost of the whole installation was about £15,000."

Meeting of the American National Electric Light Association.—This association assembled at Boston on the 9th August, under the presidency of Mr. J. F. Morrison, the meetings being continued throughout the week. The meetings of the association are held twice a year, and this is the sixth meeting since its formation in February, 1885. The previous meetings have been held at the following places in the order named:—Chicago, New York, Baltimore, Detroit, and Philadelphia. The association rapidly assumed the character of an important technical organisation, and its meetings have continuously increased in interest and extent. The following is a list of the papers read, some of which we hope to find room for either in full or in abstract:—"The Electric Light Outfit of the New (American) Cruisers," by Lieut. J. B. Murdock, U.S. Navy; "Silicon Bronze Wire Conductors," address by Dr. Waldo; "The Present Status of the Storage Battery," by Mr. C. C. Mailloux; "On Storage Batteries for Electric Lighting," by Mr. A. Reckenzaun; "On Electric Education," by Mr. Edwin R. Weekes. Most of these papers were followed by animated discussions. The reports of the following committees were also read:—On Electrical Distribution by Alternating Currents; on a Standard Wire Gauge; and on Proper Insulation of Wires and Proper Installation and Construction of Plants. The constitution of the association was also brought under review, and after much discussion certain changes were decided upon. With regard the wire gauge question, we may state at once that it was decided not to make an attempt to enforce any new gauge, but the association recommend that wires be referred to in terms of their diameters expressed as fractions of a metre. The committee on insulation and wiring drew up a programme for an elaborate and exhaustive series of tests with regard to the electrical and mechanical properties of covered wires. It was, however, discovered that the committee had not been authorised to expend any money upon work of this character, and consequently they now tendered their resignation, which was accepted. It is therefore apparently intended to allow the matter to drop for the time being. A very interesting and fairly representative exhibition of various systems of lighting was held in the Parker House, and excursions were made by the members of the association to visit various factories and installations in the neighbourhood of Boston.

University College, Bristol.—This college has been recently enabled to make a notable advance in the matter of engineering education, owing to the generosity of local firms. At a meeting held in the early part of the present year, under the presidency of Albert Fry, Esq., the desirability of instituting engineering scholarships was considered. The practical outcome of this meeting was that most of the firms of the neighbourhood agreed to institute bursaries or scholarships at

Digitized by Google

their works. The holders of these are to be nominated by the college authorities. Some will be awarded on the results of the annual examinations, while others will be reserved for deserving students who may be unable to pay the usual premiums required on entrance into works. The educational scheme adopted at Bristol does not include any attempt to impart practical workshop instruction within the college walls; but the students spend six months (April to October) in each year, acquiring practical experience in the works and drawing offices of the engineers of the West of England. This system is found to answer so well that Messrs. Stothert and Pitt, of Bath, and the Bristol Waggon Works Company propose to make it obligatory on all their pupils to attend the college courses in the winter months for the first three years of their pupilage. Several firms have also signified their willingness to take college students for short periods, so that civil engineering and electrical engineering pupils may spend one or two terms of six months in works, while at the same time mechanical engineers may have experience in two or three different establishments during their college career. In return for these concessions the Council of the College has decided to permit deserving apprentices or artisans, nominated by the local engineer, to attend the college courses at reduced rates. It is expected that about nine first class scholarships and a larger number of second class ones will be available during the coming session. The following are the names of the firms which have already put at the disposal of the college authorities one or more scholarship places in their works, on exceptionally favourable terms:—Messrs. Stothert and Pitt, Bath; The Bristol Waggon Works Company, Bristol; Messrs. Cox and Co., Falmouth; Messrs. Newall and Co., Bristol; Messrs. Willoughby Bros., Plymouth; Messrs. Bush and De Soyres, Bristol; Thos. Peckett, Atlas Engine Works, Bristol; Messrs. John Watts and Co., Bristol; Messrs. Spencer and Co., Melksham, Wilts.

Lightning Conductors.—Prof. Tyndall writes from Alp Lusgen to *The Times* of Wednesday last as follows:—"Your recent remarks on thunderstorms and their effects induce me to submit to you the following facts and considerations. Some years ago a rock lighthouse on the coast of Ireland was struck and damaged by lightning. An engineer was sent down to report on the occurrence, and as I then held the honourable and responsible post of scientific adviser to the Trinity House and Board of Trade, the report was submitted to me. The lightning conductor had been carried down the lighthouse tower, its lower extremity being carefully embedded in a stone, perforated to receive it. If the object had been to invite the lightning to strike the tower, a better arrangement could hardly have been adopted. I gave directions to have the conductor immediately prolonged, and to have added to it a large terminal plate of copper, which was to be completely submerged in the sea. The obvious convenience of a chain as a prolongation of the conductor caused the authorities in Ireland to propose it, but I was obliged to veto the adoption of the chain. The contact of link with link is never perfect. I had, moreover, beside me a portion of a chain cable through which a lightning discharge had passed, the electricity in passing from link to link encountering a resistance sufficient to enable it to partially fuse the chain. The abolition of resistance is absolutely necessary in connecting a lightning conductor with the earth, and this is done by closely embedding in the earth a plate of good conducting material and of large area. The largeness of area makes atonement for the imperfect conductivity of earth. The plate, in fact, constitutes a wide door through which the electricity passes freely into the earth, its disruptive and damaging effects being thereby avoided. These truths are elementary, but they are often neglected. I watched with interest some time ago the operation of setting up a lightning conductor on the house of a neighbour of mine in the country. The wire rope, which formed part of the conductor, was carried down the wall, and comfortably laid in the earth below, without any terminal plate whatever. I expostulated with the man who did the work, but he obviously thought he knew more about the matter than I did. I am credibly informed that this is a common way of dealing with lightning conductors by ignorant practitioners, and the Bishop of Winchester's Palace at Farnham has been mentioned to me as an edifice 'protected' in this fashion. If my informant be correct, the 'protection' is a mockery, a delusion, and a snare."

Multiplex Telephony.—Dr. Tommasi, writing in the *Moniteur Industriel*, describes a method of utilising a single wire for the simultaneous transmission of a considerable number of telephonic conversations between distant exchanges. The method is based upon the phenomenon of the persistence of the sensation of sound (analogous to the well-known persistence of the sensation of light upon the retina). That an effect of this character does exist is evident from the fact that we hear musical tones of above 16 (double) vibrations per minute as a continuous sound, and not as a succession of waves such as really exist in the atmosphere. Dr. Tommasi, therefore, proposes to make use of the principle employed in multiplex telegraphy and to cause rotating cylinders to make successive contacts between the several lines which are to be joined, each contact recurring in less than one thirty-second of a second. The cylinder must therefore rotate at a rate of about 2,000 revolutions per minute. It is further necessary that at the opposite end of the single-line wire a similar cylinder be maintained in absolutely synchronous rotation, so that the two cylinders shall always connect the same lines at the same moment. Dr. Tommasi suggests that the first cylinder should be driven by a small electro-motor, and that the synchronism of the second should be maintained "by one of the well-known methods." It is doubtful whether there is any known method by which this can be done other than Delany's adaptation of La Tour's "phonic wheel." In this case (as Dr. Tommasi points out) it will be necessary to run a separate circuit for the performance of this regulation. It must be admitted that the method does not appear very promising, because the make and break of the circuit at the rate of thirty-two times a second will itself give rise to such a noise that we can hardly expect that conversation can be conducted with any degree of comfort, even if it is possible at all. This difficulty seems to us a very grave one; if, however, it can be overcome we should be inclined to anticipate an important future for Dr. Tommasi's device. Only last week we mentioned that there are now twenty-five telephonic circuits in use between New York and Philadelphia, and it is obvious that any method which promises to do the same work with only two circuits is decidedly worth consideration. In the North of England, again, there are several trunk lines upon which (although neither so long nor so heavily wired as the Philadelphia route) the profits are yet nearly all swallowed up in the cost of maintenance. So that here again a reduction in the wire mileage would probably afford perceptible relief. We may add that Dr. Tommasi hopes to find that in practice it may be possible to work at a lower number of revolutions of the cylinder, because it may turn out that the diaphragm of the receiver has, by reason of its elasticity, a tendency to perform a larger number of vibrations than that due to the actual impulses of the magnet.

THE BRITISH ASSOCIATION MEETING, MANCHESTER, 1887.

[*By Telegraph.*]

(FROM OUR OWN CORRESPONDENT.)

MANCHESTER, WEDNESDAY EVENING.

The annual meeting of the British Association was opened this evening, in the Free Trade Hall, Manchester, under circumstances which promise to make this year's gathering one of the most memorable in the hi story of the association. The vast building was crowded with the largest assemblage of scientific men, perhaps, ever brought together in the United Kingdom, to listen to the inaugural address of Sir Henry Roscoe, M.P., the president for the year.

Prof. A. W. WILLIAMSON, in introducing the president, stated that the retiring president, Sir Wm. Dawson, had sent the following cordial words by telegram from Canada, "Regret inability to personally congratulate the association and Manchester." The learned professor then paid a graceful tribute to Sir Henry Roscoe, referring in warm terms to the eminent services which that gentleman had rendered to the cause of science and learning by his long and admirable work in the formation and development of Owens College and Victoria University.

The PRESIDENT, who was received with the greatest enthusiasm, then delivered his address [a considerable portion of which will be found in our present issue], and during the delivery, which occupied fully an hour and a-half, he carried the audience with him in breathless interest as he reviewed the history and progress of chemical science during the last half century.

At the conclusion of the address the MAYOR of MANCHESTER (Mr. Alderman Harwood) offered on behalf of the City Council and the inhabitants of Manchester a hearty welcome to the members of the association, and moved a vote of thanks to the president for his address.

Prof. GRAY, in seconding the motion, expressed the hope that the present meeting might witness the establishment of an international scientific organisation.

The PRESIDENT, in acknowledging the vote, which was carried by acclamation, said that the figures which had been furnished to him by Sir Douglas Galton showed that the number of members, as well as the amount paid into the credit of the association, was larger than it had been at any previous meeting.

THURSDAY EVENING.

To-day proceedings were commenced in the Physical Section by Prof. BALL, the president, whose address, A Dynamical Parable, was followed by the Report of the Committee on Tidal Observations. Prof. SCHUSTER then read his paper [which we print below], which he illustrated by experiments similar to those given at the Royal Society in June last.

Prof. OSBORNE REYNOLDS addressed the Mechanical Section on the illimitable advance of engineering science.

In the Chemical Section, Dr. EDWARD SCHUNK, president, delivered an address foreshadowing the time when, at the rate at which chemists are now progressing, pure chemistry will be practically exhausted, and be in the same condition as systematic botany and mineralogy at present are.

[Some electrical papers were read, but we are compelled to leave them over.]

EXPERIMENTS ON THE DISCHARGE OF ELECTRICITY THROUGH GASES.*

BY ARTHUR SCHUSTER, F.R.S., of Owens College, Manchester.

Three years ago I gave a sketch of a theory of the passage of electricity through gases, in which it was assumed that in the gaseous discharge an atom carries a definite molecular charge just as in electrolysis (*see* "Bakerian Lecture," Roy. Soc. *Proc.*, Vol. XXXIII., p. 317). I showed how this molecular charge if constant might be measured, and I have since that time worked continuously in arranging for the necessary experiments.

I have, with the help of a grant from the Royal Society, mounted a battery which gives me an electromotive force of 1,800 volts, which I hope will be sufficient for my purpose. The experiments which I have in view involve the accurate measurement of the electric potential at different points of a vessel through which a discharge is passing; but before these could be undertaken a number of intermediate questions had to be settled by experiment. As these have in this way established some definite points which I believe to be of importance, I venture to bring them before the association.

In thinking over the phenomena presented to us in vacuum tubes, I always felt a difficulty owing to our ignorance of the conditions which hold at the surface of bodies, either suspended in or near the discharge, or even at the boundary of the vessel through which the discharge is passing. It is evident enough, that if there is a flow of electricity on the surface of a non-conductor that flow must be tangential, but it is not so clear whether we are justified in concluding from this that there can be no normal forces at such surfaces, for it is not necessary that the flow should always take place along the lines of force. Imagine, for instance, a discharge to consist of particles charging at one pole, then moving, under the action of electric forces, to the other pole; and let the vacuum be sufficiently good that few or no encounters take place while it passes from one pole to another. Then bring an electrified body near the discharge. That body may deflect the particles conveying it, but unless its electrification is sufficiently large, it will not draw up the discharge to its surface, so that the normal forces on the electrified body which has been introduced need not be neutralised by the discharge.

The question is one altogether for experiment to decide. Supposing we suspend two pieces of gold leaf, as in an electroscope, at any place in a partially exhausted vessel, and render them divergent by electrification, they should collapse as soon as the discharge begins to pass, if tangential forces only can permanently exist at their surface. This I have tested by experiment and found to be the case.

A cylindrical glass vessel, 38cm. high and 15cm. wide, was divided into two approximately equal compartments by a vertical metallic screen. There was an open space of about 5 mm. between the screen and the sides of the vessel, a space about 4 cm. above, and 2·5cm. below the screen. One compartment contained two pieces of gold leaf, which could be charged from the outside. The other compartment contained two electrodes about 5cm. apart, and 2cm. from the screen; these distances could be varied during the experiment. The screen was always conducted to earth, and the electric fields on the two sides of the screen were therefore nearly independent of each other. When the gold leaves were electrified and divergent, the discharges from the induction coil passed between the electrodes on the other side, no effect could be observed at atmospheric pressure; the gold leaves remained divergent.

At a pressure of about 4·3 cm. of mercury, the effect I was looking for first appeared; when the discharge passed, the divergent leaves slowly collapsed, and as the pressure was further diminished the collapse took place more and more quickly.

We have here then, even with the discontinuous discharge, a neutralisation of all normal forces at the surface of the gold leaf.

Fig. 1 illustrates in a diagrammatic form the arrangement of the experiment, A and B being the electrodes, S the screen conducted to earth, and E the gold leaf.

In previous experiments, which were not so satisfactory from another point of view, and which I therefore do not quote, the same effects were observed both with the continuous currents from the battery and the discharges from the coil; the only difference being, that the effects due to the continuous discharge were more rapid and regular than those due to the induction coil. As soon as the pressure was sufficiently reduced

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

to allow the continuous discharge to pass the destruction of normal forces took place.

It seemed to me interesting to observe more particularly the effects of the ordinary discharges we have at our command, at atmospheric pressure. I took two light balls, and suspended them so that they could be made to diverge by electrification. The electrodes (either spheres or points) of a Voss machine were placed at a distance of 3in. from each other, and the electrified balls were placed at a distance of 9in. from the discharge. The results are contained in the following table, in which the two first columns indicate whether the electrodes of the Voss machine were points or spheres. The third column gives the electrification of the balls, and the fourth column the results :—

Negative electrode.	Positive electrode.	Balls.	Result.
Sphere	Sphere	Positive	Balls collapse slowly.
,,	,,	Negative	,, remain divergent.
Point	Point	Positive	,, collapse quickly.
,,	,,	Negative	,, remain divergent.
Sphere	,,	Positive	,, ,, ,,
,,	,,	Negative	,, collapse slowly.
Point	Sphere	Positive	,, ,, quickly.
,,	,,	Negative	,, remain divergent.

It will be seen that when the two electrodes are similar, whether spheres or points, the balls collapse when they are electrified positively only ; but that when one electrode is a sphere and another a point the balls collapse if their electrification is of the opposite nature to that supplied by the point.

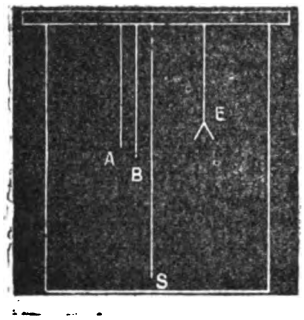

Fig. 1.

I shall refer to the theoretical bearing of these experiments at the end of the present paper, but wish at once to point out that the apparent difference in the results for positively and negatively electrified balls can be one of degree only, and not one of kind. If the balls are positively electrified, they collapse when the two electrodes are similar ; but in the other case, when the balls are negatively electrified, an equal and opposite charge will be found on the objects placed in the room or on the walls. If this positive electricity is neutralised by the discharge, the balls must ultimately collapse in this case, as well as when they were originally positively electrified. To test this argument, I placed the balls in a glass case partially covered on the inside with tinfoil. The inside of the case was nearly a cubical space of sides 37 cm. long. The front of the case was taken out, and the discharge was taken between the two points near the open front. The balls now collapsed, whatever their charge was to begin with, but more quickly when they were positive than when they were negative.

Confining ourselves to the case of a discharge between points and positive balls in its neighbourhood, the question remains whether they will collapse ultimately, whatever their distance from the discharge, or whether there is a finite distance beyond which no effect can be observed, even if the discharge be continued indefinitely. Without wishing to express any final opinion on the point, I may yet give the impression I have obtained from the experiments I have made. I believe that, whenever we have a continuous and steady discharge in an inclosure, however large, the complete neutralisation of all normal forces on surfaces through which no current goes is only a question of time, but that if there is any discontinuity in the currents (as I believe is the case in all discharges at atmospheric pressure) there is a definite distance (depending on the time intervening between two discharges) beyond which no effect will be observed.

The conclusion thus arrived at, which will be proved beyond possibility of doubt in the second part of this paper, is this : *we can only have tangential forces at the surfaces of vessels enclosing a gas through which a discharge is passing*, provided no current crosses the surface. It may be that this conclusion will appear evident to some without experimental proof, but I found it necessary to obtain definite evidence, because the fact itself has been constantly neglected and disregarded.

Thus, for instance, it is found that electrified bodies, placed outside a vessel through which a gaseous discharge is passing, do not permanently affect the appearance of the discharge, and this fact is commonly taken to prove that there can be no free electricity of either kind in the discharge. But it follows from the surface condition at the inside of the vessel, that this surface must act as a complete screen between the electrified bodies placed inside and those placed outside the vessel, and the experiment therefore proves nothing.

In similar fashion, Goldstein observed that certain actions of one negative electrode on another were destroyed when a screen was interposed between them. The results obtained in this paper give the obvious explanation of this fact.

After I had convinced myself that an electrified body placed in a partial vacuum through which an electric current is going has its electricity quickly neutralised, it was doubtful still whether this neutralisation was due to an actual discharge or merely to a covering of electrified particles of an opposite sign. The question is a vital one in all cases where potentials have to be measured. For we can only measure potentials of a gas by measuring the potential of a metal in contact with it, and if an electrified body is covered by electrified particles of a different sign, there is a finite difference of potential between the metal and the gas, and we should have to inquire carefully, in each particular case, how far such a difference would affect our conclusions.

Hittorf has measured with great success the fall of potential at different points of a vacuum tube through which a discharge was passing, and none of his principal conclusions are affected by these scruples, for he gives in his paper sufficient evidence that his method is applicable to the cases he has examined. But the purposes I have in view rendered a measurement of potential necessary under severe conditions, in which a serious error might have been introduced by assuming without verification that the potential of a metal is the same as that of a gas in contact.

Strictly speaking, the potential is always continuous as long as we are dealing with finite charges, but when a layer, the thickness of which extends to molecular distances, has its sides charged with opposite electricity, it is customary to compare the two sides of such a layer directly with each other, and neglecting the rapid variation of potential within the layer, to speak of a discontinuity of potential. It is in this sense that I am here speaking of a possible finite difference of potential between a metal and the gas in contact.

The question is settled by the principal result of this paper :—

A steady current of electricity can be obtained in air from electrodes at the ordinary temperature which are at a difference of potential of one quarter of a volt only (and probably less) ; provided that an independent current is maintained in the same closed vessel.

In other words, a continuous discharge throws the whole vessel into such a state that it will conduct for electromotive forces which I believe to be indefinitely small, but which the sensitiveness of the galvanometer I used has prevented me from tracing with certainty below a quarter of a volt. There cannot be, therefore, a finite difference of potential between a gas and a metal in contact greater than that amount.

Hittorf,* who has done more to clear up this subject than anyone else, has found already that a current from a few cells will pass crossways through a discharge in vacuo, but his auxiliary electrodes were introduced into the discharge itself,

* *Wiedemann Annalen*, Vol. VII., p. 614.

Digitized by Google

and it was doubtful, therefore, how far the results were due to the high temperature of the particles carrying the luminous discharge.* I was aiming, on the contrary, at placing the secondary electrodes as far from the main discharge as possible, and at rendering by means of screens the two electric fields as independent of each other as possible.

I need not describe all the successive experiments in which I have endeavoured to make my tests more and more severe. It will be sufficient to give an account of those experiments which I consider most conclusive.

The same vessel was used as in the previous experiment; the screen was not so long, but left a space of 10 cm. free at the bottom. Fig. 2 will explain the arrangement. SS′ is the screen, always conducted to earth; A and B are the electrodes for the main discharge; C and D are the auxiliary electrodes, which were of the form of copper cylinders, 4 cm. high, and having a diameter of 1 and 1·8cm. respectively. Their distance was 2cm., and their axis was 2cm. away from the screen. Of the main electrodes, one was 2cm. and the other 1cm. away from the screen; their distance was about 4cm. The discharge from the battery was always used. Whenever a steady current passed between A and B, an auxiliary battery of Clark cells would send a steady current between C and D, and the lower limit of electromotive force capable of producing a measurable current seemed only to depend on the delicacy of the galvanometer.

Thus, for instance, at a pressure of about $\frac{3}{4}$mm., a current of 0·11 ampere was sent from A to B; and the following currents were obtained when the poles of an auxiliary battery

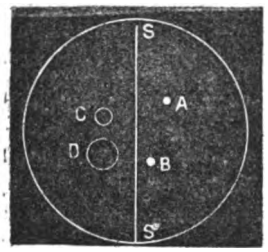

FIG. 2.

were connected with C and D, the galvanometer being inserted in the auxiliary circuit:—

40	Clark cells	0·032	micro-ampere.†
20	„	0·021	„
10	„	0·014	„
1	Leclanché	0·005	„

On another day I tried to reduce the electromotive forces still further. The galvanometer, however, had for this purpose to be rendered so astatic that the always changing torsion of the fibre suspending the mirror was a source of serious trouble; for this reason the numbers have not much value in themselves, but there was no doubt in each case as to the existence of a current. The whole effect was smaller on that day for reasons which could be traced.

1	Leclanché gave a current of	0·0010	micro-ampere.
5/18	„ „	0·0011	„
1/6	„ „	0·0003	„

The main current in these last experiments was 0·008 ampere.

An electromotive force of one-sixth Leclanché is about one-quarter of a volt, and a current has thus been obtained in a gas from an electromotive force which could not maintain a current through water.

An electromotive force of 0·1 volt gave doubtful results, but this was probably due to the experimental difficulty of detecting the current.

In some previous experiments, which, however, were not quite free from objection on other grounds, the lowest electromotive force for which the currents could be measured was 0·2 volt.

The experimental arrangement which is the best for the qualitative investigation of the effect is not the best for quantitative measurements, and I have therefore not endeavoured to follow out to any extent the quantitative laws of these currents produced by low electromotive forces. I may give, however, some facts which I have observed. The intensity of the current depends on a great many circumstances.

1. It increases rapidly with the intensity of the main discharge, and also with a reduction of pressure, as far as I have tried it (that is about $\frac{1}{2}$ mm.).

2. The intensity of the current from the auxiliary battery increases less rapidly than the electromotive force.

3. In some experiments, in which one of the electrodes of the auxiliary battery was a copper wire and the other a copper cylinder, the current was nearly always considerably stronger when the larger surface was the cathode.

4. Anything that facilitates the diffusion of gas from the main current to the auxiliary electrodes will increase the strength of the current observed. In some experiments, in which the screen separating the two fields was made of wire gauze instead of tinfoil, the currents were stronger than those given above.

5. In the arrangement shown in Fig. 2 the currents were stronger when the main electrode A was negative than when it was positive.

Considerable care has to be taken, especially when no screen is used or when it is not conducted to earth, in order to avoid leakage currents. However well the battery may originally have been insulated, the insulation always grows worse with time (owing to dust and moisture). If, then, any part of the auxiliary circuit itself is not properly insulated, we easily get a current through the galvanometer which is nothing but a branch current from the main discharge. Such a leakage current, even when it is weak, considerably increases the effects described in this paper.

These experiments show conclusively that there is nothing peculiar in the gaseous state of a body to prevent any electromotive force, however small, from producing a current. If a finite electromotive force is required under ordinary circumstances the fact cannot be accounted for, as Edlund and others have attempted to do, by a special surface resistance which has to be overcome by a finite difference of potential at the surface.

I think the facts are very well accounted for by the theory which I have proposed in my last paper. If the two atoms of a gas making up the molecule are charged by opposite electricities, but are held together in addition by molecular forces, a finite force is required to overcome the latter. But as soon as that force is overcome and the atoms themselves are set free to diffuse and constitute a current, these atoms will be able to follow any electromotive force which we may apply. If, then, we have auxiliary electrodes, these electrodes will establish their electric field, which we can never screen off completely from any other part of the vessel except by closed surfaces. The atoms, with their positive and negative charges, will diffuse across to the auxiliary electrodes and give off their electricity to them. No finite difference of potential is required in the auxiliary electrodes, because even if there is work done in making an atom interchange its positive for negative electricity, that work is undone again at the other pole, where atoms of a similar kind interchange negative for positive electricity.

This I believe to be the general explanation of the phenomena described in this paper. In order to account for the peculiar difference between positive and negative electricity which appears in the experiments done at atmospheric pressure, also those mentioned under Sec. 5 above, we must make some further supposition. I have already mentioned in my last paper that, according to the theory I have proposed, we must imagine the molecules to be broken up at the negative pole, and I believe that this fact will ultimately be found to account for this apparently unsymmetrical property of the two electricities; but I should like to strengthen my case by further experiment before going into detail on this point.

* That high temperature itself is a matter on which authorities differ. I do not desire at present to commit myself to any view which seems to involve a definition of "temperatures" under exceptional circumstances.

† 1 micro-ampere = 1 ampere × 10^{-6}.

Digitized by Google

I should like, in conclusion, to point out an important application of these results. I have last year obtained by calculation results which seem to show that the principal cause of the diurnal variation of terrestrial magnetism is to be looked for in the upper regions of the atmosphere. Prof. Balfour Stewart at various times suggested that the air currents in these regions may, owing to the lines of force of terrestrial magnetism, have electric currents circulating in them.

The difficulty against this supposition always seemed to me to lie in the fact that the electromotive forces required to start a current were larger than those which could possibly exist in the atmosphere. But as there are very likely continuous electric disturbances going on, such as we observe in auroræ and thunderstorms, the regions within which these discharges take place would act as conductors for any additional electromotive force however small, so that any regular motion, such as tidal motions, could very well produce periodic effects affecting our magnetic needles.

If these original discharges increase in importance, then, according to the results obtained in this paper, the currents due to the smaller periodic causes would increase also, and they may increase in a very rapid ratio. We know that the electric discharges in the upper regions of the atmosphere are considerably stronger at times of many sunspots, and this may account for the fact that at those times the amplitude of the daily oscillation of the magnetic needle is considerably increased.

I have had considerable assistance in these experiments from my assistant, Mr. Stanton, to whom my best thanks are due.

In the discussion which followed,

Sir W. THOMSON asked whether Prof. Schuster thought that there was sufficient connection in the atmosphere for carrying discharges so as to render the whole atmosphere conductive.

Prof. SCHUSTER replied that he thought only those particles were conductive through which the discharges actually passed.

EDISON'S PYRO-MAGNETIC DYNAMO.

At a recent meeting of the American Association for the Advancement of Science, Prof. G. F. Barker read a paper by Edison "On the Pyro-Magnetic Dynamo; a Machine for Producing Electricity Directly from Fuel." The following is an abstract:—

"The production of electricity directly from coal is a problem which has occupied the closest attention of the ablest inventors for many years. Could the enormous energy latent in coal be made to appear as electric energy by means of a simple transferring apparatus which accomplishes its result with reasonable economy, it will be conceded probably that the mechanical method of the entire world would be revolutionised thereby, and that another of those grand steps of progress would be taken of which the nineteenth century justly boasts.

"The simple production of a potential difference by means of heat is as old as Seebeck and Melloni. The science of thermo-electricity, thus originated, has been developed by Becquerel, by Peltier, by Thomson, and by Tait, and the thermo batteries of Clamond and Nöe have found many important practical uses. Our fellow member, Moses G. Farmer, worked long and assiduously in this field, producing, it is believed, the most satisfactory results as regards economy which have ever been obtained. But even these results were not very encouraging. He never succeeded in converting 1 per cent. of the energy of the coal into electric energy.

"Quite recently Lord Rayleigh has discussed with his well-known ability the law of efficiency of the thermo-battery from the standpoint of the second law of thermo-dynamics, and he concludes that for a copper iron couple, working between the extreme limits of temperature possible for these metals, a conversion of not more than one three-hundredth part of the coal energy can be hoped for. If, therefore, the result hoped for is to be attained at all, it must be looked for in some other direction obviously.

"It has long been known that the magnetism of the magnetic metals, and especially of iron, cobalt, and nickel, is markedly affected by heat. According to Becquerel, nickel loses its power of being magnetised at 400 degrees, iron at a cherry red heat, and cobalt at a white heat. Since, whenever a magnetic field varies in strength in the vicinity of a conductor a current is generated in that conductor, it occurred to me that by placing an iron core in a magnetic circuit, and by varying the magnetisability of that core by varying the temperature, it would be possible to generate a current in a coil of wire surrounding this coil. This idea constituted the essential feature of the new generator, which therefore I have called a pyro-magnetic generator of electricity.

"The principle of utilising the variation of magnetisability by heat as the basis of electric machines, though clearly applicable to generators, was first applied to the construction of a simple form of heat engine, which I have called a pyro-magnetic motor. A description of this motor will help us to understand the generator subsequently constructed. Suppose a permanent magnet having a bundle of small tubes made of thin iron placed between its poles and capable of rotation about an axis perpendicular to the plane of the magnet, after the fashion of an armature. Suppose, further, that by suitable means, such as a blast or a draught, hot air can be made to pass through these tubes so as to raise them to redness, suppose that by a flat screen symmetrically placed across the face of this bundle of tubes, and covering one-half of them, access of the heated air to the tubes beneath it is prevented. Then it follows that if this screen be so adjusted that its ends are equi-distant from the two legs of the magnet, the bundle of tubes will not rotate about the axis, since the cooler and magnetic portions of the tube-bundle, *i.e.*, those beneath the screen, will be equi-distant from the poles, and will be equally attracted on the two sides. But if the screen be turned about the axis of rotation so that one of its ends is nearer one of the poles, and the other nearer the other, then rotation of the bundle will ensue, since the portion under the screen, which is cooler, and therefore magnetisable, is continually more strongly attracted than the other and heated portion. This device acts, therefore, as a pyro-magnetic motor, the heat now passing through the tubes in such a way as to produce a dissymmetry in the lines of force of the iron-field, the rotation being due to the effort to make these symmetrical. The guard plate in this case has an action analogous to that of the commutator in an ordinary armature.

"The first experimental motor constructed on this principle was heated by means of two small Bunsen burners, arranged with an air blast, and it developed about 700 foot-pounds a minute. A second and larger motor is now about finished, which will weigh nearly 1,500 pounds, and is expected to develop about three horse-power. In both these machines electro-magnets are used in place of permanent magnets, the current to energise them being derived from an external source. In the latter machine the air for the combustion is first forced through the tubes to aid in cooling them, and then goes into the furnace at a high temperature.

"The earliest experiments in the direction of the pyro-magnetic production of electricity were made with a very simple apparatus. The success was such that the construction of a machine of sufficient size to demonstrate the feasibility of producing continuous currents on a large scale in this way was at once begun. This machine is placed upon the top of any suitable furnace, fed by a blast, so that the products of combustion are forced up through the tubes which are not covered by the guard plate, and raise them to a high temperature.

"The potential difference developed by this dynamo will obviously depend (1) upon the number of turns of wire upon the armature coils; (2) upon the temperature difference in working; (3) upon the rate of temperature variation; (4) upon the proximity of the maximum point of effect. Experiments have shown that the guard plate can probably be made to revolve 120 times a minute. Since the potential difference is proportional to the number of lines of force cut per second, it is evident that by doubling the speed or rotation, twice as many lines of force would flow across the generating coils per second and the output of energy would be quadrupled. Exactly what thickness of metal is the more suitable for the purpose; what the relative volume occupied by metal and by air space in the interstitial armature should be; what is the best diameter for this armature, or even the best metal; what the best limits of temperature, and what the best speed of rotation to produce the maximum potential difference—all these are questions which must be decided by experiments made upon the generator itself.

"The results thus far obtained lead to the conclusion that the economy of production of electric energy from fuel by the pyro-magnetic dynamo will be at least equal to and probably greater than that of any of the methods in present use. But the actual output of the dynamo will be less than that of an ordinary dynamo of the same weight. To furnish thirty sixteen-candle lights in a dwelling house would probably require a pyro-magnetic generator weighing two or three tons. Since, however, the new dynamo will not interfere with using the excess of energy of the coal for warming the house itself, and since there is no attendance required to keep it running, there would seem to be already a large field of usefulness for it. Moreover, by using the regenerative principle in connection with it, great improvement may be made in its capacity, and its practical utility may very probably equal the interesting scientific principles which it embodies."

REPORT OF THE CITY AND GUILDS INSTITUTE.

Among the many reasons which help us to accept without much regret the loss of the Technical Educational Bill in the present Session of Parliament, not the least is that which is furnished by the Ninth Annual Examination in connection with the CITY AND GUILDS OF LONDON INSTITUTE held last May, and the Report of which is now before us. The objections to the Government Bill, apart from the determining fact that there was not time to pass it, were, firstly, that it proposed to grant further powers of taxation to the School Boards; but chiefly, perhaps, because it placed the whole scheme under the guidance and virtual control of the South Kensington Science and Art Department. Neither of these objections apply to the work of the Institute which we owe to the magnificent liberality and far-seeing wisdom of the City and Guilds of London. The instruction which is being encouraged under their auspices is ostensibly technical, and in the main is of the right kind. And what renders the movement more acceptable is that it is voluntary, and that its success will be a trustworthy measure of the nation's needs and wishes in the matter of technical education—a merit which certainly could not be claimed for the Government scheme, whose conspicuous defect was its setting a sort of premium on the artificial stimulus of South Kensington being applied to fussy and ambitious School Board managers.

It is gratifying to notice year by year the steady progress that is being made with the technological examinations of the City Institute. The subjects in which examinations were held this year have increased to forty-eight, and in thirty of these the number of candidates for examination have risen considerably. The total number dealt with in the May examinations was 5,508, against 4,764 in May last year; and the number of passes has increased in a rather higher proportion. It is fair to predict that, as their sphere of operations is enlarged throughout various parts of the kingdom, the technical schools affiliated with the Central Institute will every year attract a still greater number of pupils. For our own part we have always attached quite as much importance to the Schools as to the Examinations. In this relation we notice with satisfaction that these Schools or Classes now reach the respectable number of 365, and that they extend over 121 different towns; but the number of examinations does not nearly represent the pupils attending these Schools and receiving benefit from their instruction. An increase of nearly a thousand pupils is recorded for the past year, the total number of persons receiving technical instruction in the Registered Classes of the Institute in November last amounting to 8,613.

Now of these little more than half, namely, 4,490, presented themselves for examination, the remaining 1,018 being candidates from London or Provincial colleges not included in the Institute's roll of Classes. We have therefore to face this fact, that the honours and prizes offered by the Institute do not tempt more than about 50 per cent. of the pupils to undergo an examination. It would be rash to draw any inference from this circumstance either adverse to the system of examination or the adequacy of the teaching. We draw no inferences at all; but are content with the growing popularity of the schools, the increased attendance at which is in our judgment a sufficient proof of their practical efficiency. The Examinations are, perhaps, the only way of testing this efficiency to the satisfaction of the Central Institute, but we doubt whether they are a wholly satisfactory criterion of the pupils' progress. It is more to the point that the recent Examinations "were conducted in the Laboratories of Technical Schools (where such were found) or in shops belonging to different firms" of at least one branch of instruction. It would be well if this method could be extended to all other branches; still better, perhaps, if the instruction could be given in such places, instead of in classes "where the scientific principles underlying the work" are principally taught. It is good to teach scientific principles, which no doubt conduce to the acquisition of sound technical knowledge; but if "the results of the Practical Examination were far from satisfactory," as we are told they were, when tested in the workshop, the immediate advantage of the scientific principles are not quite self-evident.

And here we are confronted by the one difficulty which interferes more than any other with the work of technical instruction, whether undertaken by a Society, an Institute, or a Government, away from and outside the practical workshop. This difficulty the Science and Art Department attempts to get over by a broad classification of subjects, which, as Prof. SILVANUS THOMPSON pointed out in his letter to *The Times* on the 15th ult., results in the demand for a little knowledge about many things in place of a thorough acquaintance with the one subject the pupil is concerned with. That is not exactly the difficulty of the City and Guilds Institute; but they have to deal with one hardly less formidable, and which is common to all schemes of the kind alike, namely, the difficulty of giving precisely the instruction needed to the very person who needs it. Tried by this test we very much fear that any and every system of instruction that attempts to take the place of, or to supersede, the old-fashioned system of apprenticeship will partially fail in its object. There will necessarily be a large expenditure of educa-

Digitized by Google

tional force which will give no return, except in the general spread of scientific knowledge, and without adding much to the special knowledge among those whom we most desire should possess it. We quite believe that the City and Guilds of London are alive to this fact; and their programme is certainly more hopeful and encouraging than any that has gone before from South Kensington or elsewhere; but it is a long way from attaining their ideal, and we are not quite sure that they are steering on the right track for it.

For one thing, they have not yet made up their minds whether the so-called Technical Instruction shall be mainly technical or largely scientific. At present they try for both, and they will probably not succeed in getting either—or if they succeed with the science it will be at the expense of technology. It is the mistake of the Board Schools over again, only on a higher level. We have more than once confessed our doubts as to what the object of the advocates of technical education really is. If it is to raise the standard of education all round, then, perhaps, they and the Board Schools may be in the right; but if the object is to create a better class of workmen and to improve their workmanship, we rather suspect they are in the wrong. The only useful education is the education that is useful, and it must differ according to the use that is going to be made of it. This we are aware is not a maxim with Board School managers; but we are a little surprised to notice that neither is it apparently a favourite with technological examiners. Mr. W. H. PREECE, for the ninth time, complains that the candidates cannot draw; and so does Mr. J. J. HOLTZAPFFELL. Here is a complaint of the right kind. Day schools ought to teach drawing, whether they teach reading or not. It is imperative a skilled workman should be able to make a drawing; it is not at all imperative he should be able to read the *Gutter Gazette*. But turning to the other Examiners, we notice that they often measure the value of the candidate's answers by the "early education" he displays. And we are left in no doubt as to what this means, for another Examiner deplores the "bad spelling" and "ill constructed" language which show that "the candidates are devoid of the rudiments of ordinary education;" while a third implicitly conveys the idea that he has rejected candidates on those grounds, notwithstanding "the practical knowledge of which in many cases they are unquestionably possessed." We hope this is not an inference to be drawn generally from the remarks of examiners more fastidious than wise in their demands for well constructed language. A *vivâ voce* examination would of course set this matter right. It is perhaps an insuperable defect of paper examinations that the indications of ignorance on the one hand and illiterateness on the other are hard to distinguish, and may easily be mistaken. We offer these criticisms in good part, and with a sincere desire to promote the cause which the City and Guilds of London have especially at heart.

CORRESPONDENCE.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Snowdon in his last letter appears to think that I have not grasped his theory *in toto*. I take it that my definition was correct as far as it went, but that I omitted to include certain important points; and I now gather from his recapitulation that—(1st) I omitted to include the exciting coils, and "that portion of the galvanic circuit which is distinct from the armature, &c.," as sources of retardation to the magnetic field; (2nd) that the E.M.F. generated in the armature and the E.M.F. generated in the stationary conductors outside is the same; and (3rd) that E.M.F. is produced whether there be current or not.

Now, I think Mr. Snowdon would have done well if he had let these pass. In the first place, no current could be produced in the exciting coils, as the field revolving, on his theory, would not cut it in the right direction, and as production of current by the field can be the only cause of retardation we may neglect such influence. Then as to the external circuit, does Mr. Snowdon mean that only that portion of the circuit that is within the field is a cause of retardation? If so, I may tell him that this may also be neglected, inasmuch as these contacts were originally constructed of carbon. I cannot think that Mr. Snowdon intends to imply that the current produced by the armature passing through these contacts is a cause of retardation; but if it does it would only make the electrical efficiency of the machine still worse than I previously stated, for now we should have a portion of the 50 per cent. that I charitably put down to useful effect in the armature wasted in useless action. Again, when Mr. Snowdon asserts that the E.M.F.'s generated in the core and armature would be the same, he states an assumption that could only hold true if the distribution of the field and velocity of cutting were the same in each; but if Mr. Snowdon will look at the longitudinal section of the field in question, as shown in one of his previous sketches, he will see that its lines of force will diminish in intensity in a radial direction from the centre of the exciting coil, and if he inspects the same field transversely—that is, in the line of the axle—he will also see that they converge to the centre of the armature. Putting, then, these two facts together with the radially varying velocity of the field itself—which, by his theory, revolves as a whole—he will understand why the distribution and cutting of that portion of the field that would traverse the core is not quite so simple a matter as it at first appears. But if for argument's sake we assume that the E.M.F.'s are equal, they would by no means be any criterion of the retardation given to the field; such retardation could only be controlled by the relation existing between the current and resistance; and this function is not expressed by E.M.F. alone. Mr. Snowdon will know practically that the more resistance he puts into the armature circuit of an ordinary dynamo, the less will be the field's reaction, and the power required to drive, notwithstanding that the E.M.F. be kept constant. Mr. Snowdon does not seem to have realised the fact that when power is applied, as in his case, to the field, the amount of retardation can only be measured by power opposed, and this when of an electrical nature must be valued by the expression $C^2 \times R$. When Mr. Snowdon says that E.M.F. is induced without current he simply gives infinity to R in the equation $E = C \times R$, and hence there is all the more reason why there should be no retardation. The function of a magnetic field is simply to determine what power can be produced under certain conditions, and this determination rests on the density of its lines and the velocity with which it is cut; but the conditions that control the amount of power actually developed are dependent entirely on the nature of the conductor, considered as a complete circuit. If the resistance of the conductor as a whole is high, its molecules will not attain a high velocity of oscillation; if the resistance is low they will, and greater power will be produced, for very much the same reason that a steam engine may be made to give greater horse-power by altering the gearing so as to permit of greater piston speed.

I must here correct some rather misleading remarks that Mr. Snowdon has thought fit to make on my previous letter. He says, in paragraph 5, "That that something (in which this reaction has its seat) is either the exciting coil (as Mr. Thompson has it), or," &c. Now, I not only never set forth the exciting coil as a cause of the reaction in the letter in question, but I never asserted it to be such in any of my previous letters; and again, further on in the same paragraph, he expresses surprise at my imputing to him that which he had clearly disclaimed, but if Mr. Snowdon had not quoted only a portion of the sentence in question it would have been evident to everybody that this was only a preparatory statement to show

Digitized by Google

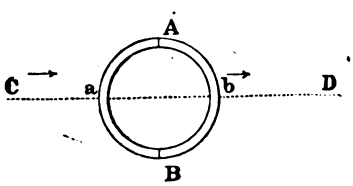
that heat generated as he suggested could not be a significant cause of retardation.—Yours, &c.,

N. G. THOMPSON.

4, Queen Victoria-street, August 31st, 1887.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your footnote to my letter you point out that in saying that "an E.M.F. is *invariably* produced when lines traverse a conductor, whether the number in the circuit changes or not," I have committed myself to an "assertion which is capable of *easy* disproof." You will, I know, forgive me if I combat this statement; for, indeed, the very reverse is the fact, and even doctors differ. I might describe an elaborate method of absolute experimental proof, but I believe the following considerations will carry the point:—Suppose the ring A*a* B*b* to move in a direction parallel to the line C D—which line marks the centre of a magnetic field which is supposed to be uniform in the direction of its length—in the place occupied by the ring. x lines of this field pass through the ring, and no change is produced in this number by the motion; for each half A*a*B – A*b*B of the moving ring cuts the same number of lines, and it is a concomitant circumstance that there is no current round the ring. If, now, a conductor which is not touched by the lines of force (A and B may be supposed to lie on the borders of the field) be applied to the points A and B, a current at once circulates from A to B through each half of the ring, and through the outer conductor.



If, under these circumstances, the resistances of the outer conductor be very small, it is well known that only a small electrical pressure can exist at the terminals A and B, but if the outer resistance be gradually increased until it is very large, then, as is well known, the pressure at the terminals gradually increases until it practically reaches the maximum E.M.F. corresponding to the rate at which the ring cuts the lines. Now when the resistance of the external portion of the circuit is practically infinite, the terminal E.M.F. has its maximum value. Use for this portion of the circuit a bent rod of glass—a shocking bad conductor, truly, but still not an absolute non-conductor, and constituting, with the ring, a mathematical circuit—the E.M.F. has not been scared away. Current has, to all practical purposes, ceased, but E.M.F. is at its maximum. Dispense with the glass portion of the circuit, and consider that you have one of air in its place, and you have still maximum electrical pressure.

It is true I did not describe in full detail the non-polar dynamo which is illustrated in to-day's *Electrician*; but I am sure you would recognise the toad-stool field-magnet, and the identity of the principle of the moving systems. I did not state my purpose in asking the information I did for fear of appearing ridiculous.—Yours, &c.,

R. SNOWDON.

Staveley, August 26th, 1887.

[Mr. Snowdon is, we fear, guilty of the logical fallacy of a *petitio principii*. He undertakes to show that an E.M.F. is *invariably* generated when a conductor traverses a uniform field; he then admits, with unaffected candour, that a plane-closed circuit moving through a uniform field parallel to its own plane generates no E.M.F. on itself, but he immediately asks us to upset these conditions by extending the circuit so as to include a portion beyond the (uniform) field. We are not quite sure whether Mr. Snowdon means his ring to move parallel to the lines of force or across them. In the former case we see no reason to suppose that an E.M.F. is necessarily generated even under the second condition of the circuit. In the latter case, without decisive experimental proof, the assertion that the absence of current when the circuit is confined to the ring alone must necessarily be due to two opposing E.M.F.'s can hardly be justified in our present state of knowledge; at the best, the argument is reduced to a verbal quibble, in which we should be perfectly willing to yield our correspondent the victory.—ED. *E.*]

ARC LIGHT PROJECTORS IN THE ROYAL NAVY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a note in your issue of last week you ask if any good reason can be advanced for the continued use of hand, in preference to automatic, regulation for arc light projectors in our navy.

I write to state a few arguments in favour of the former system, and I may say that my experience with projectors has been derived during several years at sea on board of warships with both types of lamps.

A well known trouble with arc lamps using heavy currents, and consequently large carbons, is the excessive tendency to "mushroom," and this even with the very best quality of carbon. Although the services for feeding the arc are now very perfect, I am unacquainted with any arc lamp adapted for heavy currents which would automatically open an arc which had been closed or "throttled" by "mushrooms."

Again, the irregularity in the consumption of carbons caused by this "mushrooming" constantly destroys the focus even of the most perfect automatic lamps. On the other hand, a little practice with the hand regulator will enable the blue jacket easily to keep the focus perfect.

The rolling of the ship, or the shock caused by the firing of guns, not only seriously affects the feed of the automatic lamp, but often completely disarranges its apparatus.

As the projector is often placed in a position where it is much affected by the vibration of the ship, a very rigid lamp is essential. It will be admitted that no automatic lamp can compare with the hand regulator for rigidity. Its parts are very simple, and may easily be repaired or replaced by a ship's artificer.

Regarding the objection to the hand regulator, that it gives the man in charge a double duty, it has not been my experience that the blue jacket in charge of the projector considers his duty either difficult or oppressive.

The coloration of the beams from the projectors during the recent naval evolutions would seem to indicate that the carbons used were not of a high quality, or that some of the attendants were not sufficiently instructed.—Yours, &c.,

ALFRED MAYOR.

Forth Bridge Works, South Queensferry, N.B.,
August 29th, 1887.

THE SUPPOSED NEW FORCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be obliged if you will find me space in *The Electrician* to thank Mr. Nock for his remarks and very concise enunciation of his views. I will endeavour, as far as possible, in the future to render my meaning clear to physicists as well as physiologists.—Yours, &c.,

RICHARD C. SHETTLE.

London-street, Reading, August 30th, 1887.

THE VAN RYSSELBERGHE SYSTEM.

The *Bulletin* of the Belgian Society of Electricans contains an interesting communication on the Van Rysselberghe system of simultaneous telegraph and telephone communication, showing the extent to which the system is at present in use. The first experiments were carried out by Van Rysselberghe on the line between Brussels and Paris in the month of May, 1881. A more complete set of experiments were made in the following year between Brussels, Antwerp, and Ostend; but the first practical use of the system was on the line between Amsterdam and Haarlem, a distance of 20 kilometres. This line was opened for the public service on the 27th October, 1883. In the same year the Belgian Chambers passed a vote authorising the application of the system to the existing telegraph lines. It was not, however,

Digitized by Google

until the autumn of the following year (1884) that the first Belgian line (between Brussels and Antwerp) was finally opened for public service.

Since that time thirty-seven circuits of this nature have been established in different parts of the country, showing a total length of 7,206 kilometres of wire; and it appears that there are in Belgium only 260 kilometres of inter-urban telephone lines which are worked independently of the telegraph. In France the first line was opened on January 2, 1885, between Rouen and Havre. There are now seven lines equipped upon this system, namely Rouen-Havre, Rouen-Louviers, Paris-Reims, Paris-Rouen, Paris-Havre, Paris-Lille, Paris-Marseilles. The international line between Paris and Brussels has also recently been adapted for telegraph work. Total length of lines in France on the Van Rysselberghe system 4,045 kilometres. There are also about 420 kilometres of inter-urban telephone wires independent of the telegraph. In Germany the following lines are in operation:—Berlin - Halle, Berlin - Stettin, Berlin - Dessau, Berlin - Oranienbourg, Breslau-Beuthen, Munich-Augsburg, Nurenberg - Bainberg, Stuttgard - Heilbron, Stuttgard - Broeblingen, Stuttgard - Ulm, Stuttgard - Friedrichshafer—total length of wire 2,512 kilometres. In Austria there is only one line, that between Vienna and Brunn, length 288 kilometres. In Switzerland there are six lines of this character—Geneva-Lausanne (three wires by different routes), Lausanne-Vevey, Zürich - Mannendorf, Bale - Zürich—total length 536 kilometres. In Holland, besides the original Amsterdam-Haarlem line, there are now two others from the Hague to neighbouring villages. There is also a line of 55 kilometres between two towns in the Dutch Indies, Weltevreden and Buitenzorg (Java). In Spain there are lines between Madrid, Burgos, Valencia, and Granada. In Portugal there is a line from Lisbon to Oporto, and thence to Cintra; and in Denmark a line will shortly be opened between Rudkjobing and Vanmenas. This completes the list of European lines on the Van Rysselberghe system, which are either already in use or will be opened very shortly. In addition to these, several important lines are projected in Germany, Austria, Spain, Portugal, Italy, Roumania, Russia, Turkey, and Greece, but the work on these has not yet commenced. The following tables summarise the above statements:—

	Kilometres.
Germany	2,512
Austria	288
Belgium	7,206
Denmark	10
Spain	140
France	4,044
Holland and Colonies	386
Switzerland	536
Total	15,122

The total length of the lines projected amounts to 5,050 kilometres. The system is also in use to a certain extent in the United States, in the Argentine Republic, in Uruguay, in Brazil, in Venezuela, in Mexico, in China and Japan; in fact, it extends more or less over the whole civilised world, with the glaring exception of England and the British Colonies. We have frequently expressed our own estimate of the value of the system, which is, in brief, that wherever telegraphy is intended to play second fiddle then Van Rysselberghe's system is of great value. If, as in the Paris-Brussels case, we have a line built expressly with regard to the telephone service, there can be no difficulty in working off a moderate amount of telegraphy in addition. But the converse does not hold good, and hence the system is not adapted to the majority of English lines. These is no reason, however, why the system should not prove useful in some of our country districts and in many of the Colonies.

The article from which we have prepared the above abstract would have been more useful if it had distinguished in all cases between lines especially built for the double service and old telegraph lines to which the system had been *successfully* applied. We doubt whether the latter class is a very extensive one.

RADIATION FROM DULL AND BRIGHT SURFACES.*

BY J. T. BOTTOMLEY, M.A., F.R.S.E.

In connection with an investigation on heat radiation which I have been carrying on for some time past, and on which I recently presented a communication to the Royal Society, I have had occasion to examine the important results obtained by Mr. Mortimer Evans on the radiation of light and heat from bright and dull surfaces when incandescent (Roy. Soc. *Proc.*, Vol. XL., 1886, p. 207); and I have repeated and verified some of his experiments. Mr. Evans experimented on carbon filaments of incandescent lamps; and in calculating, for my own use, the resistances of the filaments at different degrees of incandescence I was led to an unexpected result, and hence to an investigation of which I desire just now to offer a preliminary notice.

In order to explain, it is necessary for me to state briefly the object and nature of Mr. Evans's experiments. Their object was the comparison of the radiation from surfaces having a bright, polished appearance with that from dull surfaces having the appearance of lampblack; and he was led to an important practical conclusion as to the superior light-giving efficiency of the brilliant-looking filament. For these comparisons the *same* filament was treated in such ways as to alter the surface from dull to bright and back again. It was taken out of the glass globe for the purpose, and after treatment placed in a fresh globe, which was then exhausted. The lamps thus constructed and reconstructed were tested at various candle-powers, the energy for each candle-power being determined.

The tables given in Mr. Evans's paper show for the filaments in different conditions the potential and the current required to maintain different candle-powers from four candles upward. Using his numbers, and supposing Ohm's† law to hold for the carbon filaments, I have calculated the resistances of the filaments at different candle-powers.

Two filaments used by Mr. Evans afforded satisfactory data for my calculations. They are designated in his paper D, DD, DDD, and C, CC, CCC. They had been treated in the following manner:—The filaments D and C were "flashed" so as to have a dull surface with the appearance of lampblack. DD and CC are the same filaments flashed so as to have a brilliant surface, which, though black, has something of the appearance of frosted silver. DDD, CCC, are the same filaments again rendered dull as at first. The following table shows the volts, amperes, and calculated resistances at the candle-powers given in the left-hand column:—

TABLE I.—*Carbon D.*

	D.			DD.			DDD.		
Candles.	Volts.	Amp.	Resist.	Volts.	Amp.	Resist.	Volts.	Amp.	Resist.
4	46·5	1·02	45·6	37·3	1·	37·3	34	1·28	26·6
10	52·5	1·20	43·8	42·	1·13	37·17	38·5	1·52	25·3
20	58·3	1·40	41·6	47·8	1·32	36·29	43	1·77	24·3
40	65	1·62	40·1	52·5	1·53	34·3	48	2·06	23·3
50	68	1·70	40·0	54·2	1·60	33·9	50	2·12	23·6*

TABLE II.—*Carbon C.*

	C.			CC.			CCC.		
Candles.	Volts.	Amp.	Resist.	Volts.	Amp.	Resist.	Volts.	Amp.	Resist.
4	45	0·86	52·33	34	0·95	35·79	39	1·16	33·62
10	56	1·12	49·99	39	1·12	34·82	44·5	1·38	32·24
20	62	1·28	48·43	44	1·28	34·37	49·5	1·53	32·37*

* The two results which appear last in these tables seem anomalous, and therefore I have not used them in my calculation.

Now, if we suppose the resistance of the carbon filament to depend on the temperature, the resistance diminishing as the temperature increases (though very probably not in simple proportion); and if (as we should do in the case of a metallic wire) we use these resistances in order to compare the temperatures of the filaments at different candle-powers, we are led to a remarkable result. Taking the filament D, and dividing the resistances of D, DD, and DDD at four candles by those at the higher candle-powers, we obtain numbers which may be looked on as ratios of conductances, and which may be taken as indicating, though not exactly representing, corresponding changes in the temperature of the carbon.

* Paper communicated to the Royal Society by Sir W. Thomson, F.R.S.

†I have already commenced an investigation into the question of the conformity of carbon filaments of different temperatures with Ohm's law.

TABLE III.

To pass from—						D.	DD.	DDD.
4 candles	to	10 candles	increase of conductance is	from 1 to		1·041	1·006	1·047
4	,,	20	,,	,,		1·096	1·028	1·095
4	,,	40	,,	,,		1·137	1·087	1·137
4	,,	50	,,	,,		1·14	1·100	—

The filament C gives confirmatory results, but unfortunately it seems to have broken down early in the condition CCC. I find, however—

TABLE IV.

To pass from—						C.	CC.	CCC.
4 candles	to	10 candles	increase of conductance is	from 1 to		1·047	1·028	1·043
4	,,	20	,,	,,		1·081	1·041	—

Comparing these numbers we are led to the result that, if we admit the assumptions I have made, the temperature to which the carbon must be raised in order that it may give out light of a definite candle-power is higher when the surface is in the dull condition than when it is in a brilliant metallic-looking state.

This result was to me so unexpected that I proceeded to test it directly by the following experiments :—Two glass tubes, similar in every respect, were constructed, containing two precisely similar platinum wires cut from the same hank, which had been specially drawn for me some months before by Messrs. Matthey and Johnson. One of the wires was in its natural bright condition, while the other was covered with the thinnest possible coating of lampblack, which was put on by passing the wire quickly and steadily through the flame of a paraffin lamp. The construction of these tubes is shown in Fig. 1. The platinum wire *a b* is kept stretched by two spiral springs of copper, being silver-soldered to two extremities of these springs. Two loops *l* at the other extremities of the spirals pass over two pieces of glass rod *g g*, *g g*, which are passed in by side tubes, blown on the main glass tube ; and the spirals pull on the glass rods. The ends of the side tubes are sealed up after the glass rods are in their places, with the exception of one, which is used for connecting to the Sprengel pump, and is finally sealed when a complete vacuum has been made. Flexible copper electrodes, *e e*, are silver-soldered to the loops at the ends of the copper springs, and to multiple platinum wires which are sealed into the glass tube at A and B. Fine platinum wires, *p p*, are attached to the main wire, and are brought through the sides of the glass tube ; and these serve as potential testing electrodes. The two tubes and their fittings are, as has been said, perfectly similar in every respect, except that one platinum wire is covered with an extremely thin coating of lampblack.

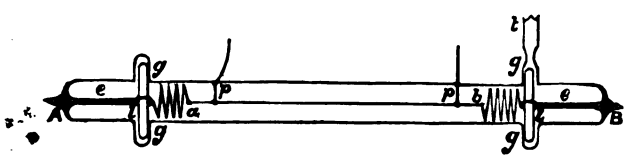

FIG. 1.

The two tubes were attached to a glass fork, and were simultaneously exhausted with the Sprengel pump down to about two millionths of an atmosphere, all the well-understood precautions as to drying, &c., being carefully attended to ; and they were then at the same moment sealed off from the pump. The length of the tubes A B is 22in. over all ; and the internal diameter of the tubes ⅞in. The distance between the potential electrodes *p p* is 15in. (38·1 centimetres). The diameter of the platinum wire *a b* is 0·022in. (0·0599 centimetres). On testing the resistance of the two platinums between the potential electrodes, *cold* and at the same temperature, it was found to be the same for both to less than one one-thousandth part of the resistance of either of them.

The tubes having been prepared as described above, they were connected in parallel arc to a battery of six secondary cells in series, a variable platinoid wire being added in series with the tube containing the bright platinum, in order to regulate its current ; and a rheostat designed for carrying strong currents was used to control the whole. The connections will be readily understood from a glance at Fig. 2.

With the rheostat and the variable platinoid wire the two platinums were then brought to the same incandescence (as judged by the eye) at various brightnesses from just visible redness up to nearly white heat ; and the resistances of the platinums between the potential electrodes were measured by means of a high resistance reflecting galvanometer, suitably arranged, with shunt and interposed resistance, for the purpose in hand.

The result of my experiments is to bear out completely the deduction which I had made from Mr. Mortimer Evans's numbers ; and to show that the temperature which produces, for example, the appearance of a certain red heat, is very much higher when the surface of the heated body is dulled than when it is bright as in a polished metal. I am not yet prepared to give a definite numerical comparison ; but in order to show that the difference of temperatures referred to amounts to many degrees of temperature, I may be allowed to give the following statement :—

The two wires being at the same dull red heat, which from previous experience I estimate at perhaps 600deg. C., in the case of the bright-surfaced wire, the ratio of the resistance of the lampblacked platinum to the bright platinum was 130 : 93. Platinums differ very much as to variation of resistance with temperature ; but in most specimens the resistance is doubled, when the temperature is raised from 0deg. C. to a temperature of from 300deg. C. to 400deg. C., and for any particular platinum wire the change in resistance is almost in simple proportion to the change in temperature. From this statement it may be judged that the difference of temperatures between the two platinums, dull and bright, when giving out the same light, was a great many degrees centigrade.

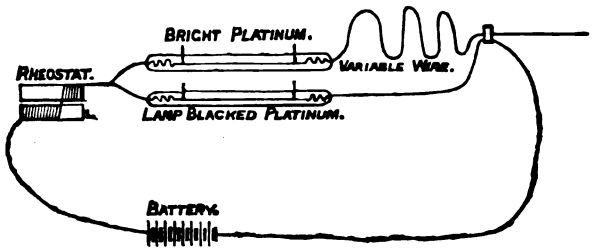

FIG. 2.

The difference of temperatures of the two glass envelopes was also very striking. The glass tube containing the bright wire was not even unpleasantly warm ; while in the case of the other it was so hot as to blister the skin of the hand, and in this connection it is to be remembered that the vacuum in the two tubes was the same.

I propose as soon as possible to continue this investigation and render it more complete.

THE SUPPOSED "NEW FORCE."

BY R. C. SHETTLE, M.D.

(Continued from page 321.)

Experiment 3.—The suspending silk was removed from the supporting rod, and replaced, after giving it half a turn, so as to bring the minor north magnetic pole next to the magnet without any torsion ; the position was again diagonal, and upon completing the circuit the rotation recurred, and finally the minim pole, after similar oscillations, came nearly to rest, as shown in Fig. 6.

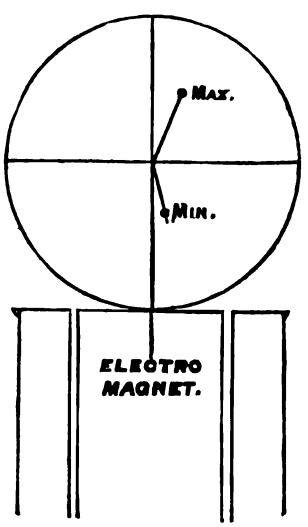

FIG 6.

Experiment 4.—Upon the circuit being broken the spheroid rotated, until the maxim pole came within the hemisphere next the magnet ; on the circuit being completed the rotation was much

Digitized by Google

accelerated, and after the usual angular oscillations the spheroid tended to come to rest, as in Fig. 5.

Experiment 5.—The two arms of the electro-magnet were now used, and placed at an angle to each other, so as to permit of the spheroid being placed between them, as in Fig. 7. The battery

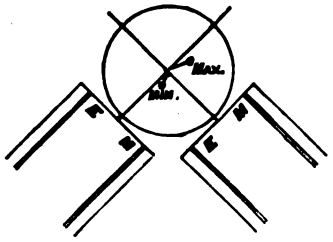

FIG. 7.

current was then turned on, and the spheroid commenced to rotate, the movement passing through the usual angle, and the spheroid tended to come to rest opposite the pole in front of which its maxim pole was situated.

Experiment 6.—The effect of torsion was next shown by rotating the spheroid once upon its axis, and then setting it free, the battery current being maintained, but imparting as little rotary motion as possible. Rotation at once commenced in an endeavour to remove the imparted torsion, but the magnetic force of the maxim pole prevented its passing away from the influence of the magnetic pole in front of which it was placed. This was repeated several times, after which the sphere was rotated once more in the same direction, and again set free, when the same phenomena recurred. The proof of the torsion being considerable in the last case was demonstrated by breaking battery contact, when the spheroid immediately commenced rotating upon its axis in the opposite direction, and the momentum gave it four complete rotations; rotations which were reversed, and reversed again until the sphere was taken down from its position.

Experiment 7.—Two electro-magnets were arranged parallel, one resting on the other, the north and south poles pointing in opposite directions. The spheroid was suspended so that its centre was in a line with the division between the two arms of the electro-magnets, the north pole of the top electro-magnet being directed to the northern hemisphere of the spheroid, and the south pole of the other electro-magnet to the southern hemisphere. Before making battery contact, the poles of the north hemisphere of the spheroid were transverse to the magnetic-field, and the spheroid was at rest without torsion. Upon making battery contact, after an interval of about four seconds, rotation of the spheroid commenced from east to west, in the direction of the hands of a clock; this continued until the poles of the spheroid had arranged themselves in a line with the axis of the electro-magnet; they then oscillated in the opposite direction through about 45deg., stopped, and then again moved from east to west. These oscillations were repeated, but to a diminished extent, when moving from west to east, but always going to the original point in the first direction.

Experiment 8.—When battery current was broken, the spheroid at the time moving from west to east, the oscillations in that direction continued through 180deg. This brought the maxim pole opposite and immediately in front of the north pole of the upper electro-magnet. When in this position, battery contact was re-made, and the maxim pole was brought to rest after a few slight oscillations, in a position on the side of the sphere nearest the electro-magnet.

Experiment 9.—Battery contact was broken, and the direction of the current reversed, so as to convert the pole of the upper electro-magnet nearest the spheroid into a south pole, and the lower electro-magnet into a north pole. The spheroid when at rest now, as in Experiment No. 1, hung without torsion, with its poles transverse to the plane of the electro-magnets. Contact being made, *the same motions of the spheroid were repeated as when the E.M. poles were of opposite signs.* Battery contact was broken, and the maxim pole of the spheroid was allowed to swing back by torsion from west to east.

Experiment 10.—When about 20 deg. beyond the axis of the E.M. poles battery contact was remade, and the maxim pole, after two or three slight oscillations, came to rest on the axis of the electro-magnet poles, and nearest to them; thus showing indifference to their sign.

Experiment 11.—The spheroid was now lowered so that a plane passing horizontally through the two north poles might be in a line with the axis of the lower electro-magnet, which, owing to the direction of the current, was a north pole.

When thus suspended and at rest, without torsion, the poles being transverse to the axis of the electro-magnet, battery contact was made, and axial rotation was established sufficient to bring the maxim pole of the spheroid round to the axis of the magnet.

Experiment 12.—When the current was reversed so as to convert the north pole of the electro-magnet into a south pole, the motion was precisely the same in direction and amount.

Experiment 13.—The spheroid was now raised so that a plane passing horizontally through its south poles was brought level with the axis of the upper limb of the electro-magnet. The spheroid was first subjected to the action of the north and then of the south pole of this limb, and it was found that either pole of the spheroid, when brought under the influence of the arm, was attracted, and after a few oscillations was held.

These experiments were repeated many times and modified, but always with the same results.

Remarks.—The foregoing experiments prove (1) that when insulated copper wire has been cut into lengths and wound in right and left hand helical directions, so that the terminals converge to four centres on opposite sides of a spheroidal mass, such a mass, when suspended before a single pole of an electro-magnet, is converted into a peculiar form of magnet, which manifests polarity at each of the centres to which the terminals of the strands of wire have been drawn.

(2) That the polar phenomena continue so long as the battery current circulates in the electro-magnet.*

(3) That axial rotation of such a spheroid through a certain arc of a circle, by each pole, is established.

(4) Indifference to the sign of the pole of the electro-magnet, is as the pole of the spheroid which is nearest to the magnet attracted.

(5) That time is an essential element in the production of the phenomena, as is shown by an interval elapsing between making battery contact and the motion of the spheroid.

(6) The identity of magnetic and mechanical force, for as the strands of wire run in helical directions round the spheroid, each strand represents a lever by which motion is effected.

SPHEROID No. 2.

A second spheroid was constructed, commencing with a spheroid of willow wood $\frac{3}{4}$in. in diameter. Into the equatorial line, and the sites of the various magnetic poles, pins were driven, as in No. 1. 322ft. of No. ·0075 silk-covered German silver wire were laid on, as already described with the first spheroid.

Experiment 14.—Thus prepared, the spheroid was suspended by a single filament of cocoon silk in front of one of the poles of the electro-magnet. Upon making battery contact axial rotation occurred just as described with spheroid No. 1, either pole being attracted as it happened to be most in proximity to the electro-magnet; but the rotations were quicker and shorter when the pole representing the maxim terrestrial pole held such position.

Experiment 15.—It was considered desirable to test the magnetic character of the india rubber insulite. For this purpose a spheroid was made of the substance, and suspended in front of the electro-magnet by a single filament of cocoon silk. Upon making battery contact no perceptible motion, attraction, repulsion, or axial rotation could be detected.

SPHEROID No. 3.

The surface of a willow wood sphere 1in. in diameter was divided by an equatorial line. Fifty-two pins were driven into this equatorial line, and one about $\frac{1}{4}$ of an inch on either side of a pole which had been pierced from pole to pole through the centre of each hemisphere. Thus prepared, the sphere was covered with silk-covered copper wire, laid on between the pins as in spheroids Nos. 1 and 2, except that in spheroid No. 3 only one layer of wire was laid on. The terminals of the wires of one side of the equatorial line were drawn in a left hand helical direction *to one geographical pole;* the terminals on the other side were taken with a right hand helical twist *to the other pole.* The wires on this spheroid were tied into position by means of thread without insulite.

Experiment 16.—The spheroid was suspended by a single fibre of cocoon silk, and then subjected to the influence of a single pole of the electro-magnet. No motion was perceptible.

The wires were next unwound; one half—*i.e.*, 26, were drawn to one of the pins on one side of the pole, the other 26 to the other pin in the same hemisphere; the terminals of the strands in the other hemisphere were taken to the other two pins, the right and left hand helical direction being again imparted. The wires were tied into position by means of thread.

Experiment 17.—The spheroid, prepared as described, was suspended and subjected to the influence of the magnetic pole, just as it was prior to the re-winding. Axial rotations were set up, as in the case of Nos. 1 and 2.

(To be continued.)

* There appears to be only one mode of explaining these phenomena, viz., by currents being induced in the copper wire of the spheroid by the magnet. If this be so, then such currents are not *momentary* at the time of making and breaking battery contact, but *permanent.*

THE BRITISH ASSOCIATION MEETING AT MANCHESTER, 1887.

THE PRESIDENT'S ADDRESS.

The following is the Presidential Address of Sir HENRY E. ROSCOE, M.P., D.C.L., LL.D., PH.D., F.R.S., V.P.C.S, delivered to the members of the British Association at Manchester on Wednesday last:—

Manchester, distinguished as the birthplace of two of the greatest discoveries of modern science, heartily welcomes to-day for the third time the members and friends of the British Association for the Advancement of Science. On the occasion of our first meeting in this city in the year 1842, the President, Lord Francis Egerton, commenced his address with a touching allusion to the veteran of science, John Dalton, the great chemist, the discoverer of the laws of chemical combination, the framer of the atomic theory upon which the modern science of chemistry may truly be said to be based. Lord Francis Egerton said: "Manchester is still the residence of one whose name is uttered with respect wherever science is cultivated, who is here to-night to enjoy the honours due to a long career of persevering devotion to knowledge, and to receive from myself, if he will condescend to do so, the expression of my own deep personal regret that increase of years, which to him up to this hour has been but increase of wisdom, should have rendered him in respect of mere bodily strength unable to fill on this occasion an office which in his case would have received more honour than it could confer. I do regret that any cause should have prevented the present meeting in his native town from being associated with the name"—and here I must ask you to allow me to exchange the name of Dalton in 1842 for that of Joule in 1887, and to add again in the words of the President of the former year that I would gladly have served as a doorkeeper in any house where Joule, the father of science in Manchester, was enjoying his just pre-eminence. For it is indeed true that the mantle of John Dalton has fallen on the shoulders of one well worthy to wear it, one to whom science owes a debt of gratitude not less than that which it willingly pays to the memory of the originator of the atomic theory. James Prescott Joule it was who, in his determination of the mechanical equivalent of heat, about the very year of our first Manchester meeting, gave to the world of science the results of experiments which placed beyond reach of doubt or cavil the greatest and most far-reaching scientific principle of modern times, namely, that of the conservation of energy. This, to use the words of Tyndall, is indeed a generalisation of conspicuous grandeur fit to take rank with the principle of gravitation, more momentous, if that be possible, combining as it does the energies of the material universe into an organic whole, and enabling the eye of science to follow the flying shuttles of the universal power as it weaves what the Erdgeist in "Faust" calls "the living garment of God."

It is well, therefore, for us to remember, in the midst of the turmoil of our active industrial and commercial life, that Manchester not only well represents the energy of England in these practical directions, but that it possesses even higher claims to our regard and respect as being the seat of discoveries of which the value not only to pure science is momentous, but which also lie at the foundation of all our material progress and all our industrial success. For without a knowledge of the laws of chemical combination all the marvellous results with which modern industrial chemistry has astonished the world could not have been achieved, whilst the knowledge of the quantitative relations existing between the several forms of energy, and the possibility of expressing their amount in terms of ordinary mechanics, are matters which now constitute the life breath of every branch of applied science. For example, before Dalton's discovery every manufacturer of oil of vitriol—a substance now made each week in thousands of tons within a few miles of this spot—every manufacturer had his own notions of the quantity of sulphur which he ought to burn in order to make a certain weight of sulphuric acid, but he had no idea that only a given weight of sulphur can unite with a certain quantity of oxygen and of water to form the acid, and that an excess of any one of the component parts was not only useless but harmful. Thus, and in tens of thousands of other instances, Dalton replaced rule of thumb by scientific principle. In like manner the applications of Joule's determination of the mechanical equivalent of heat are even more general; the increase and measurement of the efficiency of our steam engines and the power of our dynamos are only two of the numerous examples which might be adduced of the practical value of Joule's work.

If the place calls up these thoughts, the time of our meeting also awakens memories of no less interest, in the recollection that we this year celebrate the Jubilee of Her Most Gracious Majesty's accession to the throne. It is right that the members of the British Association for the Advancement of Science should do so with heart and voice, for although science requires and demands no royal patronage, we thereby express the feeling which must be uppermost in the hearts of all men of science, the feeling of thankfulness that we have lived in an age which has witnessed an advance in our knowledge of nature, and a consequent improvement in the physical, and let us trust also in the moral and intellectual, well being of the people hitherto unknown; an age with which the name of Victoria will ever be associated.

To give even a sketch of this progress, to trace even in the merest outline the salient points of the general history of science during the fifty momentous years of Her Majesty's reign, is a task far beyond my limited powers. It must suffice for me to point out to you, to the best of my ability, some few of the steps of that progress as evidenced in the one branch of science with which I am most familiar, and with which I am more closely concerned—the science of chemistry.

In the year 1837 chemistry was a very different science from that existing at the present moment. Priestley, it is true, had discovered oxygen, Lavoisier had placed the phenomena of combustion on their true basis, Davy had decomposed the alkalis, Faraday had liquefied many of the gases, Dalton had enunciated the laws of chemical combination by weight, and Gay Lussac had pointed out the fact that a simple volumetric relation governs the combination of the gases. But we then possessed no knowledge of chemical dynamics, we were then altogether unable to explain the meaning of the heat given off in the act of chemical combination. The atomic theory was, indeed, accepted, but we were as ignorant of the mode of action of the atoms and as incapable of explaining their mutual relationship as were the ancient Greek philosophers. Fifty years ago, too, the connection existing between the laws of life, vegetable and animal, and the phenomena of inorganic chemistry, was ill understood. The idea that the functions of living beings are controlled by the same forces, chemical and physical, which regulate the changes occurring in the inanimate world, was then one held by only a very few of the foremost thinkers of the time. Vital force was a term in everyone's mouth, an expression useful, as Goethe says, to disguise our ignorance, for

Wo die Begriffe fehlen,
Da tritt ein Wort zur rechten Zeit sich ein.

Indeed, the pioneer of the chemistry of life, Liebig himself, cannot quite shake himself free from the bonds of orthodox opinion, and he who first placed the phenomena of life on a true basis cannot trust his chemical principles to conduct the affairs of the body, but makes an appeal to vital force to help him out of his difficulties; as when in the body politic an unruly mob requires the presence and action of physical force to restrain it and to bring its members under the saving influence of law and order, so, too, according to Liebig's views, in the body corporeal a continued conflict between the chemical forces and the vital power occurs throughout life, in which the latter, when it prevails, ensures health and a continuance of life, but of which defeat insures disease or death. The picture presented to the student of to-day is a very different one. We now believe that no such conflict is possible, but that life is governed by chemical and physical forces, even though we cannot in every case explain its phenomena in terms of these forces; that whether these tend to continue or to end existence depends upon their nature and amount, and that disease and death are as much a consequence of the operation of chemical and physical laws as are health and life.

Looking back again to our point of departure fifty years ago, let us for a moment glance at Dalton's labours, and compare his views and those of his contemporaries with the ideas which now prevail. In the first place it is well to remember that the keystone of his atomic theory lies not so much in the idea of the existence and the indivisible nature of the particles of matter—though this idea was so firmly implanted in his mind that, being questioned on one occasion on the subject, he said to his friend the late Mr. Ransome, "Thou knowst it must be so, for no man can split an atom"—as in the assumption that the weights in these particles are different. Thus whilst each of the ultimate particles of oxygen has the same weight as every other particle of oxygen, and each atom of hydrogen, for example, has the same weight as every other particle of hydrogen, the oxygen atom is sixteen times heavier than that of hydrogen, and so on for the atoms of every chemical element, each having its own special weight. It was this discovery of Dalton, together with the further one that the elements combine in the proportions indicated by the relative weights of their atoms or in multiples of these proportions, which at once changed chemistry from a qualitative to a quantitative science, making the old invocation prophetic, "God created all things according to measure and to weight"

The researches of chemists and physicists during the last fifty years have not only strengthened but broadened the foundations of the great Manchester philosopher's discoveries. It is true that his original numbers, obtained by crude and inaccurate methods, have been replaced by more exact figures, but his laws of combination and his atomic explanation of those laws stand as the great bulwarks of our science.

On the present occasion it is interesting to remember that within a stone's-throw of this place is the small room belonging to our Literary and Philosophical Society which served Dalton as his laboratory. Here, with the simplest of all possible apparatus—a few cups, penny ink bottles, rough balances, and self-made thermometers and barometers—Dalton accomplished his great results. Here he patiently worked, marshalling facts to support his great theory, for as an explanation of his laborious experimental investigations the wise old man says:—"Having been in my progress so often misled by taking for granted the results of others, I have determined to write as little as possible but what I can attest by my own experience." Nor ought we when here assembled to forget that the last three of Dalton's experimental essays—one of which, on a new method of measuring water of crystallisation, contained more than the germ of a great discovery—were communicated to our Chemical Section in 1842, and that this was the last memorable act of his scientific life. In this last of his contributions to science, as in his first, his method of procedure was that which has been marked out as the most fruitful by almost all the great searchers after nature's secrets, namely, the assumption of a certain view as a working hypothesis, and the subsequent institution of experiment to bring this hypothesis to a test of reality upon which a legitimate theory is afterwards to be based. "Dalton," as Henry well says, "valued detailed facts mainly, if not solely, as the stepping stones to comprehensive generalisations."

Next let us ask what light the research of the last fifty years has thrown on the subject of the Daltonian atoms, first, as regards their size; secondly, in respect to their indivisibility and mutual relationships; and thirdly, as regards their motions. As regards the size and shape of the atoms Dalton offered no opinion, for he had no experimental grounds on which to form it, believing that they were inconceivably small and altogether beyond the grasp of our senses aided by the most powerful appliances of art. He was in the habit of representing his atoms and their combinations diagrammatically as round discs or spheres made of

Digitized by Google

wood, by means of which he was fond of illustrating his theory. But such mechanical illustrations are not without their danger, for I well remember the answer given by a pupil to a question on the atomic theory: "Atoms are round balls of wood invented by Dr. Dalton." So determinedly, indeed, did he adhere to his mechanical method of representing the chemical atoms and their combinations that he could not be prevailed upon to adopt the system of chemical formulæ introduced by Berzelius and now universally employed. In a letter addressed to Graham in April, 1837, he writes: "Berzelius' symbols are horrifying. A young student in chemistry might as soon learn Hebrew as make himself acquainted with them." And again: "They appear to me equally to perplex the adepts in science, to discourage the learner, as well as to cloud the beauty and simplicity of the atomic theory." But modern research has accomplished, as regards the size of the atom, at any rate to a certain extent, what Dalton regarded as impossible. Thus in 1865 Loschmidt, of Vienna, by a train of reasoning which I cannot now stop to explain, came to the conclusion that the diameter of an atom of oxygen or nitrogen was $\frac{1}{10,000,000}$ of a centimetre. With the highest known magnifying power we can distinguish the $\frac{1}{40,000}$ part of a centimetre; if now we imagine a cubic box each of whose sides has the above length, such a box when filled with air will contain from 60 to 100 millions of atoms of oxygen and nitrogen. A few years later William Thomson extended the methods of atomic measurement, and came to the conclusion that the distance between the centres of contiguous molecule is less than $\frac{1}{5,000,000}$ and greater than $\frac{1}{1,000,000,000}$ of a centimetre; or, to put it in language more suited to the ordinary mind, Thomson asks us to imagine a drop of water magnified up to the size of the earth, and then tells us that the coarseness of the graining of such a mass would be something between a heap of small shot and a heap of cricket balls. Or again, to take Clifford's illustration, you know that our best microscopes magnify from 6,000 to 8,000 times; a microscope which would magnify that result as much again would show the molecular structure of water. Or again, to put it in another form, if we suppose that the minutest organism we can now see were provided with equally powerful microscopes, these beings would be able to see the atoms.

Next, as to the indivisibility of the atom, involving also the question as to the relationships between the atomic weights and properties of the several elementary bodies. Taking Dalton's aphorism, "Thou knowst no man can split an atom," as expressing the view of the enunciator of the atomic theory, let us see how far this idea is borne out by subsequent work. In the first place, Thomas Thomson, the first exponent of Dalton's generalisation, was torn by conflicting beliefs until he found peace in the hypothesis of Prout, that the atomic weights of all the so-called elements are multiples of a common unit, which doctrine he sought to establish, as Thorpe remarks, by some of the very worst quantitative determinations to be found in chemical literature, though here I may add that they were not so incorrect as Dalton's original numbers. Coming down to a somewhat later date, Graham, whose life was devoted to finding what the motion of an atom was, freed himself from the bondage of the Daltonian aphorism, and defined the atom not as a thing which cannot be divided, but as one which has not been divided. With him, as with Lucretius, as Angus Smith remarks, the original atom may be far down. But speculative ideas respecting the constitution of matter have been the scientific relaxation of many minds from olden time to the present. In the mind of the early Greek the action of the atom as one substance taking various forms by unlimited combinations was sufficient to account for all the phenomena of the world. And Dalton himself, though upholding the indivisibility of his ultimate particles, says: "We do not know that any of the bodies denominated elementary are absolutely indecomposable." Again, Boyle, treating of the origin of form and quality, says: "There is one universal matter common to all bodies—an extended divisible and impenetrable substance." Then Graham in another place expresses a similar thought when he writes: "It is conceivable that the various kinds of matter now recognised as different elementary substances may possess one and the same ultimate or atomic molecules existing in different conditions of movement. The essential unity of matter is an hypothesis in harmony with the equal action of gravity upon all bodies." What experimental evidence is now before us bearing upon these interesting speculations? In the first place, then, the space of fifty years has completely changed the face of the inquiry. Not only has the number of distinct well-established elementary bodies increased from fifty-three in 1837 to seventy in 1887 (not including the *twenty* or more new elements recently said to have been discovered by Krüss and Nilson in certain rare Scandinavian minerals), but the properties of these elements have been studied, and are now known to us with a degree of precision then undreamt of. So that relationships existing between these bodies which fifty years ago were undiscernable are now clearly manifest, and it is to these relationships that I would for a moment ask your attention. I have already stated that Dalton measured the relative weights of the ultimate particles by assuming hydrogen as the unit, and that Prout believed that on this basis the atomic weight of all the other elements would be found to be multiples of the atomic weights of hydrogen, thus indicating that an intimate constitutional relation exists between hydrogen and all the other elements.

Since the days of Dalton and Prout the truth or otherwise of Prout's law has been keenly contested by the most eminent chemists of all countries. The inquiry is a purely experimental one, and only those who have a special knowledge of the difficulties which surround such inquiries can form an idea of the amount of labour and self-sacrifice borne by such men as Dumas, Stas, and Marignac in carrying out delicate researches on the atomic weights of the elements. What is, then, the result of these most laborious experiments? It is that, whilst the atomic weights of the elements are not exactly either multiples of the unit or of half the unit, many of the numbers expressing most accurately the weight of the atom approximate so closely to a multiple of that of hydrogen that we are constrained to admit that these approximations cannot be a mere matter of chance, but that some reason must exist for them. What that reason is, and why a close approximation and yet something short of absolute identity exists, is as yet hidden behind the veil; but who is there that doubts that when this association celebrates its centenary this veil will have been lifted, and this occult but fundamental question of atomic philosophy shall have been brought into the clear light of day?

But these are by no means all the relationships which modern science has discovered with respect to the atoms of our chemical elements. So long ago as 1829 Döbereiner pointed out that certain groups of elements exist, presenting in all their properties strongly marked family characteristics, and this was afterwards extended and insisted upon by Dumas. We find, for example, in the well-known group of chlorine, bromine, and iodine, these resemblances well developed, accompanied, moreover, by a proportional graduation in their chemical and physical properties. Thus, to take the most important of all their characters, the atomic weight of the middle term is the mean of the atomic weights of the two extremes. But these groups of triads appeared to be unconnected in any way with one another, nor did they seem to bear any relation to the far larger number of the elements not exhibiting these peculiarities. Things remained in this condition until 1863, when Newlands threw fresh light upon the subject, showing a far-reaching series of relationships. For the first time we thus obtained a glance into the mode in which the elements are connected together, but, like so many new discoveries, this did not meet with the recognition which we now see it deserves. But whilst England thus had the honour of first opening up this new path, it is to Germany and to Russia that we must look for the consummation of the idea. Germany, in the person of Lothar Meyer, keeps, as it is wont to do, strictly within the limits of known facts. Russia, in the person of Mendelejeff, being of a somewhat more imaginative nature, not only seizes the facts which are proved, but ventures on prophecy. These chemists, amongst whom Carnelley must be named, agree in placing all the elementary bodies in a certain regular sequence, thus bringing to light a periodic recurrence of analogous chemical and physical properties, on account of which the arrangement is termed the periodic system of the elements.

In order to endeavour to render this somewhat complicated matter clear to you, I may perhaps be allowed to employ a simile. Let us, if you please, imagine a series of human families, a French one, represented by Dumas; an English one, by name Newlands; a German one, the family of Lothar Meyer; and lastly a Russian one, that of Mendelejeff. Let us next imagine the names of these chemists placed in a horizontal line in the order I have mentioned. Then let us write under each the name of his father, and again, in the next lower line, that of his grandfather, followed by that of his great-grandfather, and so on. Let us next write against each of these names the number of years which has elapsed since the birth of the individual. We shall then find that these numbers regularly increase by a definite amount, *i.e.*, by the average age of a generation, which will be approximately the same in all the four families. Comparing the ages of the chemists themselves we shall observe certain differences, but these are small in comparison with the period which has elapsed since the birth of any of their ancestors. Now, each individual in this series of family trees represents a chemical element; and just as each family is distinguished by certain idiosyncrasies, so each group of the elementary bodies thus arranged shows distinct signs of consanguinity. But more than this, it not unfrequently happens that the history and peculiarities of some member of a family may have been lost, even if the memory of a more remote and more famous ancestor may be preserved, although it is clear that such an individual must have had an existence. In such a case Francis Galton would not hesitate from the characteristics of the other members to reproduce the physical and even the mental peculiarities of the missing member, and should genealogical research bring to light the true personal appearance and mental qualities of the man, these will be found to coincide with Galton's estimate.

Such predictions and such verifications have been made in the case of no less than three of our chemical elements. Thus, Mendelejeff pointed out that if, in the future, certain lacunæ in his table were to be filled, they must be filled by elements possessing chemical and physical properties which he accurately specified. Since that time these gaps have actually been stopped by the discovery of Gallium by Lecoq de Boisbaudron, of Scandium by Nilson, and of Germanium by Winkler, and their properties, both physical and chemical, as determined by their discoverers, agree absolutely with those predicted by the Russian chemist. Nay, more than this, we not unfrequently have had to deal with chemical foundlings, elements whose parentage is quite unknown to us. A careful examination of the personality of such waifs has enabled us to restore them to the family from which they have been separated by an unkind fate, and to give them that position in chemical society to which they are entitled. These remarkable results, though they by no means furnish a proof of the supposition already referred to, viz., that the elements are derived from a common source, clearly point in this direction, and lend some degree of colour to the speculations of those whose scientific imagination, wearying of dry facts, revels in picturing to itself an elemental Bathybius, and in applying to the inanimate, laws of evolution similar to those which rule the animate world. Nor is there wanting other evidence regarding this inquiry, for here heat, the great analyser, is brought into court. The main portion of the evidence consists in the fact that distinct chemical individuals capable of existence at low temperatures are incapable of existence at high ones, but split up into new materials possessing a less complicated structure than the original. And here it may be well to emphasise the distinction which the chemist draws between the atom and the molecule, the latter being a more or less complicated aggregation of atoms, and especially to point out the fundamental difference between the

Digitized by Google

question of separating the atoms in the molecule and that of splitting up the atom itself. The decompositions above referred to are, in fact, not confined to compound bodies, for Victor Meyer has proved in the case of iodine that the molecule at high temperatures is broken to atoms, and J. J. Thomson has added to our knowledge by showing that this breaking up of the molecule may be effected not only by heat vibrations, but likewise by the electrical discharge at a comparatively low temperature.

How, far, now, has this process of simplification been carried? Have the atoms of our present elements been made to yield? To this a negative answer must undoubtedly be given, for even the highest of terrestrial temperatures, that of the electric spark, has failed to shake any one of these atoms in two. That this is the case has been shown by the results with which spectrum analysis, that new and fascinating branch of science, has enriched our knowledge, for that spectrum analysis does give us most valuable aid in determining the varying molecular conditions of matter is admitted by all. Let us see how this bears on the question of the decomposition of the elements, and let us suppose for a moment that certain of our present elements, instead of being distinct substances, were made up of common ingredients, and that these compound elements, if I may be allowed to use so incongruous a term, are split up at the temperature of the electric spark into less complicated molecules. Then the spectroscopic examination of such a body must indicate the existence of these common ingredients by the appearance in the spark spectra of these elements of identical bright lines. Coincidences of this kind have indeed been observed, but on careful examination these have been shown to be due either to the presence of some one of the other elements as an impurity or to insufficient observational power. This absence of coincident lines admits, however, of two explanations—either that the elements are not decomposed at the temperature of the electric spark, or, what appears to me a much more improbable supposition, each one of the numbers of bright lines exhibited by every element indicates the existence of a separate constituent, no two of this enormous number being identical.

Terrestrial analysis having thus failed to furnish favourable evidence, we are compelled to see if any information is forthcoming from the chemistry of the sun and stars. And here I would remark that it is not my purpose now to dilate on the wonders which this branch of modern science has revealed. It is sufficient to remind you that chemists thus have the means placed at their disposal of ascertaining with certainty the presence of elements well known on this earth in fixed stars so far distant that we are now receiving the light which emanated from them perhaps even thousands of years ago.

Since Bunsen and Kirchhoff's original discovery in 1859, the labours of many men of science of all countries have largely increased our knowledge of the chemical constitution of the sun and stars, and to no one does science owe more in this direction than to Lockyer and Huggins in this country, and to Young in the New England beyond the seas. Lockyer has of late years devoted his attention chiefly to the varying nature of the bright lines seen under different conditions of time and place on the solar surface, and from these observations he has drawn the inference that the matching observed by Kirchhoff between, for instance, the iron lines as seen in our laboratories and those visible in the sun, has fallen to the ground. He further explains this want of uniformity by the fact that at the higher transcendental temperatures of the sun the substance which we know here as iron is resolved into separate components. Other experimentalists, however, while accepting Lockyer's facts as to the variations in the solar spectrum, do not admit his conclusions, and would rather explain the phenomena by the well-known differences which occur in the spectra of all the elements when their molecules are subject to change of temperature or change of position.

Further, arguments in favour of this idea of the evolution of the elements have been adduced from the phenomena presented by the spectra of the fixed stars. It is well known that some of these shine with a white, others with a red, and others again with a blue light; and the spectroscope, especially under the hands of Huggins, has shown that the chemical constitution of these stars is different. The white stars, of which Sirius may be taken as a type, exhibit a much less complicated spectrum than the orange and the red stars; the spectra of the latter remind us more of those of the metalloids and of chemical compounds than of the metals. Hence it has been argued that in the white, presumably the hottest, stars a celestial dissociation of our terrestrial elements may have taken place, whilst in the cooler stars, probably the red, combination even may occur. But even in the white stars we have no *direct* evidence that a decomposition of any terrestrial atom has taken place; indeed, we learn that the hydrogen atom, as we know it here, can endure unscathed the inconceivably fierce temperature of stars presumably many times more fervent than our sun, as Sirius and Vega.

Taking all these matters into consideration, we need not be surprised if the earthbound chemist should, in the absence of celestial evidence which is incontestable, continue, for the present at least, and until fresh evidence is forthcoming, to regard the elements as the unalterable foundation stones upon which his science is based.

Pursuing another line of inquiry on this subject, Crookes has added a remarkable contribution to the question of the possibility of decomposing the elements. With his well-known experimental prowess, he has discovered a new and beautiful series of phenomena, and has shown that the phosphorescent lights emitted by certain chemical compounds, especially the rare earths, under an electric discharge in a high vacuum exhibit peculiar and characteristic lines. For the purpose of obtaining his material Crookes started from a substance believed by chemists to be homogeneous, such, for example, as the rare earth yttria, and succeeded by a long series of fractional precipitations in obtaining products which yield different phosphorescent spectra, although when tested by the ordinary methods of what we may term high temperature spectroscopy, they appear to be the one substance employed at the starting point. The other touchstone by which the identity, or otherwise, of these various products might be ascertained, viz., the determination of their atomic weights, has not, as yet, engaged Crookes's attention. In explanation of the singular phenomena the discoverer suggests two possibilities. First, that the bodies yielding the different phosphorescent spectra are different elementary constituents of the substance which we call yttria. Of, if this be objected to because they all yield the same spark spectrum, he adopts the very reasonable view that the Daltonian atom is probably, as we have seen, a system of chemical complexity; and adds to this the idea that these complex atoms are not all of exactly the same constitution and weight, the differences, however, being so slight that their detection has hitherto eluded our most delicate tests, with the exception of this one of phosphorescence in a vacuum. To these two explanations, Marignac, in a discussion of Crookes' results, adds a third. It having been shown by Crookes himself that the presence of the minutest traces of foreign bodies produce remarkable alterations in the phosphorescent spectra, Marignac suggests that in the course of the thousands of separations which must be made before these differences become manifest, traces of foreign bodies may have been accidentally introduced, or, being present in the original material, may have accumulated to a different extent in the various fractions, their presence being indicated by the only test by which they can now be detected. Which of these three explanations is the true one must be left to future experiment to decide.

We must now pass from the statics to the dynamics of chemistry; that is, from the consideration of the atoms at rest to that of the atoms in motion. Here again we are indebted to John Dalton for the first step in this direction, for he showed that the particles of a gas are constantly flying about in all directions; that is, that gases diffuse into one another, as an escape of coal gas from a burner, for example, soon makes itself perceptible throughout the room. Dalton, whose mind was constantly engaged in studying the molecular condition of gases, first showed that a light gas cannot rest upon a heavier gas as oil upon water, but that an interpenetration of each gas by the other takes place. It is, however, to Graham's experiments, made rather more than half a century ago, that we are indebted for the discovery of the law regulating these molecular motions of gases, proving that their relative rates of diffusion are inversely proportional to the square roots of their densities, so that oxygen being sixteen times heavier than hydrogen, their relative rates of diffusion are 1 and 4.

But whilst Dalton and Graham indicated that the atoms are in a continual state of motion, it is to Joule that we owe the first accurate determination of the rate of that motion. At the Swansea meeting in 1848 Joule read a paper before Section A "On the Mechanical Equivalent of Heat, and on the Constitution of Elastic Fluids." In this paper Joule remarks that whether we conceive the particles to be revolving round one another according to the hypothesis of Davy, or flying about in every direction according to Herepath's view, the pressure of the gas will be in proportion to the *vis viva* of its particles. "Thus it may be shown that the particles of hydrogen at the barometrical pressure of 30in. at a temperature of 60deg. must move with a velocity of 6225·54ft. per second in order to produce a pressure of 14·7141bs. on the square inch;" or, to put it in other words, a molecular cannonade or hailstorm of particles, at the above rate—a rate, we must remember, far exceeding that of a cannon ball—is maintained against the bounding surface.

We can, however, go a step further and calculate with Clerk Maxwell the number of times in which this hydrogen molecule, moving at the rate of 70 miles per minute, strikes against others of the vibrating swarm, and we learn that in one second of time it must knock against others no less than 18 thousand million times.

And here we may pause and dwell for a moment on the reflection that in nature there is no such thing as great or small, and that the structure of the smallest particle, invisible even to our most searching vision, may be as complicated as that of any one of the heavenly bodies which circle round our sun.

But how does this wonderful atomic motion affect our chemistry? Can chemical science or chemical phenomena throw light upon this motion, or can this motion explain any of the known phenomena of our science? I have already said that Lavoisier left untouched the dynamics of combustion. He could not explain why a fixed and unalterable amount of heat is in most cases emitted but in some cases absorbed when chemical combination takes place. What Lavoisier left unexplained Joule has made clear. On August 25, 1843, Joule read a short communication, I am glad to remember, before the Chemical Section of our Association, meeting that year at Cork, containing an announcement of a discovery which was to revolutionise modern science. This consisted in the determination of the mechanical equivalent of heat, in proving by accurate experiment that the expenditure of energy equal to that developed by the weight of 772lb. falling through one foot at Manchester, the temperature of one pound of water can be raised 1deg. Fahr. In other words, every change in the arrangement of the particles is accompanied by a definite evolution or an absorption of heat. In all such cases the molecular energy leaves the potential to assume the kinetic form, or *vice versâ*. Heat is evolved by the clashing of the atoms, and this amount is fixed and definite.

Thus it is to Joule we owe the foundation of chemical dynamics and the basis of thermal chemistry. As the conservation of mass or the principle of the indestructibility of matter forms the basis of chemical statics, so the principle of the conservation of energy* constitutes the foundation of chemical dynamics. Change in the form of matter and change in the form of energy are the universal accompaniments of every chemical operation. Here again it is to Joule we owe the proof of the truth of

* "The total energy of any material system is a quantity which can neither be increased nor diminished by any action between the parts of the system, though it may be transformed into any of the forms of which energy is susceptible."—MAXWELL.

Digitized by Google

this principle in another direction, viz., that when electrical energy is developed by chemical change a corresponding quantity of chemical energy disappears. Energy as defined by Maxwell is the power of doing work, and work is the act of producing a change of configuration in a system in opposition to a force which resists that change. Chemical action produces such a change of configuration in the molecules. Hence, as Maxwell says, "a complete knowledge of the mode in which the potential energy of a system varies with the configuration would enable us to predict every possible motion of the system under the action of given external forces, provided we were able to overcome the purely mathematical difficulties of the calculation." The object of thermal chemistry is to measure these changes of energy by thermal methods, and to connect these with chemical changes, to estimate the attractions of the atoms and molecules to which the name of chemical affinity has been applied, and thus to solve the most fundamental problem of chemical science. How far has modern research approached the solution of this most difficult problem? How far can we answer the questions, what is the amount of the forces at work in these chemical changes? What laws govern these forces? Well, even in spite of the results with which recent researches—especially the remarkable ones of the Danish philosopher Thomsen—have enriched us, we must acknowledge that we are yet scarcely in sight of Maxwell's position of successful prediction. Thermal chemistry, we must acknowledge, is even yet in its infancy; it is, however, an infant of sturdy growth, likely to do good work in the world, and to be a credit to him who is its acknowledged father, as well as to those who have so carefully tended it in its early years.

But recent investigation in another direction bids fair even to eclipse the results which have been obtained by the examination of thermal phenomena. And this lies in the region of electrical chemistry. Faraday's work relating to conductivity of chemical substances has been already referred to, and this has been since substantiated and extended to pure substances by Kohlrausch. It has been shown, for example, that the resistance of absolutely pure water is almost an infinite quantity. But a small quantity of an acid, such as acetic or butyric acid, greatly increases the conductivity; but more than this, it is possible by determination of the conductivity of a mixture of water with these two acids to arrive at a conclusion as to the partition of the molecules of the water between the acids. Such a partition, however, implies a change of position, and therefore we are furnished with a means of recognising the motion of the molecules in a liquid, and of determining its amount. Thus it has been found that the hindrance to molecular motion is more affected by the chemical character of the liquid than by physical characters such as viscosity. We have seen that chemical change is always accompanied by molecular motion, and further evidence of the truth of this is gained from the extraordinary chemical inactivity of pure unmixed substances. Thus pure anhydrous hydrochloric acid does not act upon lime, whereas the addition of even a trace of moisture sets up a most active chemical change, and hundreds of other examples of a similar kind might be stated. Bearing in mind that these pure anhydrous compounds do not conduct, we are led to the conclusion that an intimate relation exists between chemical activity and conductivity. And we need not stop here; for a method is indicated, indeed, by which it will be possible to arrive at a measure of chemical affinity from determination of conductivity. It has, indeed, been already shown that the rate of change in the saponification of acetic ether is directly proportional to the conductivity of the liquid employed.

Such wide-reaching inquiries into new and fertile fields, in which we seem to come into nearer touch with the molecular state of matter, and within a measurable distance of accurate mathematical expression, leads to confident hope that Lord Rayleigh's pregnant words at Montreal may ere long be realised:—"It is from the further study of electrolysis that we may expect to gain improved views as to the nature of chemical reactions, and of the forces concerned in bringing them about; and I cannot help thinking that the next great advance, of which we already have some foreshadowing, will come on this side."

There is, perhaps, no branch of our science in which the doctrine of the Daltonian atom plays a more conspicuous part than in organic chemistry or the chemistry of the carbon compounds, as there is certainly none in which such wonderful progress has been made during the past fifty years. One of the most striking and perplexing discoveries made rather more than half a century ago was that chemical compounds could exist which, whilst possessing an identical chemical composition—that is, containing the same percentage quantity of their constituents—are essentially distinct chemical substances exhibiting different properties. Dalton was the first to point out the existence of such substances, and to suggest that the difference was to be ascribed to a different or to a multiple arrangement of the constituent atoms. Faraday soon afterwards proved that this supposition was correct, and the research of Liebig and Wöhler on the identity of composition of the salts of fulminic and cyanic acid gave further confirmation to the conclusion, leading Faraday to remark that "now we are taught to look for bodies composed of the same elements in the same proportion but differing in their qualities, they may probably multiply upon us." How true this prophecy has become we may gather from the fact that we now know of thousands of cases of this kind, and that we are able not only to explain the reason of their difference by virtue of the varying position of the atoms within the molecule, but even to predict the number of distinct variations in which any given chemical compound can possibly exist. How large this number may become may be understood from the fact that, for example, one chemical compound, a hydro-carbon containing thirteen atoms of carbon combined with twenty-eight atoms of hydrogen, can be shown to be capable of existing in no less than 802 distinct forms.

Experiment in every case in which it has been applied has proved the truth of such a prediction, so that the chemist has no need to apply the cogent argument sometimes said to be used by experimentalists enamoured of pet theories, "When facts do not agree with theory, so much the worse for the facts!" This power of successful prediction constitutes a high-water mark in science, for it indicates that the theory upon which such a power is based is a true one. But if the Daltonian atom forms the foundation of this theory, it is upon a knowledge of the mode of arrangement of these atoms and on a recognition of their distinctive properties that the superstructure of modern organic chemistry rests. Certainly it does appear almost to verge on the miraculous that chemists should now be able to ascertain with certainty the relative position of atoms in a molecule so minute that millions upon millions, like the angels in the schoolmen's discussion, can stand on a needle's point. And yet this process of orientation is one which is accomplished every day in our laboratories, and one which more than any other has led to results of a startling character. Still, this sword to open the oyster of science would have been wanting to us if we had not taken a step farther than Dalton did, in the recognition of the distinctive nature of the elemental atoms. We now assume on good grounds that the atom of each element possesses distinct capabilities of combination; some a single capability, others a double, others a triple, and others, again, a fourfold combining capacity. The germs of this theory of valency, one of the most fruitful of modern chemical ideas, were enunciated by Frankland in 1852, but the definite explanation of the linking of atoms, of the tetrad nature of the carbon atoms, their power of combination, and of the difference in structure between the fatty and aromatic series of compounds, was first pointed out by Kekulé in 1857; though we must not forget that this great principle was foreshadowed so long ago as 1833 from a physical point of view by Faraday in his well-known laws of electrolysis, and that it is to Helmholtz in his celebrated Faraday lecture that we owe the complete elucidation of the subject, for, whilst Faraday has shown that the number of the atoms electrolytically deposited is in the inverse ratio of their valencies, Helmholtz has explained this by the fact that the quantity of electricity with which each atom is associated is directly proportional to its valency.

Amongst the tetrad class of elements, carbon, the distinctive element of organic compounds, finds its place; and the remarkable fact that the number of carbon compounds far exceeds that of all the other elements put together receives its explanation. For these carbon atoms not only possess four means of grasping other atoms, but these four-handed carbon atoms have a strong partiality for each other's company, and readily attach themselves hand in hand to form open chains or closed rings to which the atoms of other elements join to grasp the unoccupied carbon hand, and thus to yield a dancing company in which all hands are locked together. Such a group, each individual occupying a given position with reference to the others, constitutes the organic molecule. When, in such a company, the individual members change hands, a new combination is formed. And as in such an assembly the eye can follow the changing positions of the individual members, so the chemist can recognise in his molecule the position of the several atoms, and explain by this the fact that each arrangement constitutes a new chemical compound possessing different properties, and account in this way for the decompositions which each differently constituted molecule is found to undergo. Chemists are, however, not content with representing the arrangement of the atoms in one plane, as on a sheet of paper, but attempt to express the position of the atoms in space. In this way it is possible to explain certain observed differences in isomeric bodies which otherwise baffled our efforts. To Van t'Hoff, in the first instance, and more recently to Wislicenus, chemistry is indebted for work in this direction, which throws light on hitherto obscure phenomena, and points the way to still further and more important advances.

It is this knowledge of the mode in which the atoms in the molecule are arranged, this power of determining the nature of this arrangement, which has given to organic chemistry the impetus which has overcome so many experimental obstacles, and given rise to such unlooked for results. Organic chemistry has now become synthetic. In 1837 we were able to build up but very few and very simple organic compounds from their elements; indeed the views of chemists were much divided as to the possibility of such a thing. Both Gmelin and Berzelius argued that organic compounds, unlike inorganic bodies, cannot be built up from their elements. Organic compounds were generally believed to be special products of the so-called vital force, and it was only intuitive minds, like those of Liebig and Wöhler, who foresaw what was coming, and wrote in 1837 strongly against this view, asserting that the artificial production in our laboratories of all organic substances, so far as they do not constitute a living organism, is not only probable but certain. Indeed, they went a step farther, and predicted that sugar, morphia, salicine, will all thus be prepared; a prophecy which, I need scarcely remind you, has been after fifty years fulfilled, for at the present time we can prepare an artificial sweetening principle, an artificial alkaloid, and salicine.

(To be continued.)

THE INSTITUTION OF CIVIL ENGINEERS.

In our last issue we gave a list of the subjects of an electrical nature upon which communications are invited by the Council of the Institution of Civil Engineers. For the benefit of those of our readers who may not happen to be acquainted with the conditions under which these papers are received, we subjoin the information which accompanies the list:—

"The Council of the Institution of Civil Engineers invites original communications on the subjects included in the following list, as well as on any other questions of professional interest. For approved papers the council has the power to award premiums, arising out of special funds bequeathed for the purpose, the particulars of which are as under:—

"1. The *Telford Fund*, left in trust, the interest to be expended in

Digitized by Google

annual premiums, under the direction of the council.' This bequest (with accumulations of dividends) produces £260 annually.

"The *Manby Donation*, of the value of about £10 a year, given 'to form a fund for an annual premium or premiums for papers read at the meetings.'

"3. The *Miller Fund*, bequeathed by the testator 'for the purpose of forming a fund for providing premiums or prizes for the students of the said institution, upon the principle of the Telford Fund.' This fund (with accumulations of dividends) realises £150 per annum. Out of this fund the council has established a scholarship, called 'The Miller Scholarship of the Institution of Civil Engineers,' and is prepared to award one such scholarship, not exceeding £40 in value, each year, and tenable for three years.

"4. The *Howard Bequest*, directed by the testator to be applied 'for the purpose of presenting periodically a prize or medal to the author of a treatise on any of the uses or properties of iron, or to the inventor of some new and valuable process relating thereto, such author or inventor being a member, graduate, or associate of the said institution.' The annual income amounts to nearly £16. It has been arranged to award this prize every five years, commencing from 1887. The next award will therefore be made in 1892.

"The council will not make any award unless a communication of adequate merit is received, but will give more than one premium if there are several deserving memoirs on the same subject. In the adjudication of the premiums no distinction will be made between essays received from members of the institution or strangers, whether natives or foreigners, except in the cases of the Miller and the Howard bequests, which are limited by the donors.

Instructions for Preparing Communications.

"In writing these essays the use of the first person should be avoided. They should be legibly transcribed on foolscap paper, on one side only, leaving a margin on the left side, in order that the sheets may be bound. Every paper must be prefaced by an abstract of its contents, not exceeding 1,500 words in length.

"Illustrations, when necessary, should be drawn on tracing-paper, to as small a scale as is consistent with distinctness, but in no case should any figure exceed 6½ inches in height. When an illustrated communication is accepted for reading, a series of diagrams will be required sufficiently large and boldly coloured to be clearly visible at a distance of 60ft. These diagrams will be returned.

"Papers which have been read at the meetings of other societies, or have been published, cannot be read at a meeting of the institution, nor be admitted in competition for the premiums.

"The communications must be forwarded to the secretary of the institution, from whom any further information may be obtained. There is no specified date for the delivery of MSS., as when a paper is not in time for one session it is dealt with in the succeeding one."

COMPANIES' MEETINGS.

Lancashire and Cheshire Telephonic Exchange Company.

The sixth annual meeting of this Company was held on Monday last at the Memorial Hall, Manchester, under the presidency of Mr. Charles Moseley, chairman of the Company.

The SECRETARY and GENERAL MANAGER (Mr. Kenneth MacIver) read the notice convening the meeting, and the report of the Directors, which appeared in our last issue, was taken as read.

The CHAIRMAN, in moving the adoption of the report, said it was a source of great satisfaction to the Directors to have gone through another financial year with such very satisfactory results. The revenue showed an increase of nearly £10,000 on the previous year. The income from their trunk wires showed a considerable increase, and the tendency seemed to be growing to use the wires between long distance towns. The mileage of the company had increased during the year from 6,203 to 7,253, and the probability was that the mileage would go on increasing year after year. The number of messages sent over the wires during the year was eleven and a-half millions, being an increase of half a million. The average cost of the message was 1d. The Company were now seeking to extend the radius of their operations. They contemplated making arrangements with the National Company for connection with Staffordshire towns in the same way as arrangements had been made with the same Company for communication with Yorkshire, and before long it was hoped that their connection with the Midland district would be complete. They also hoped to connect with the salt district, and with Chester and with North Wales. Arrangements were being made with a view to the introduction of a new switching apparatus in Manchester, similar to the one which had answered so satisfactorily in Liverpool, and advantage was being taken of this opportunity to concentrate into one switch room all the telephone wires at present dispersed over three separate switch rooms in different parts of the city. A reduction had been made during the year in maintenance charges of £300, and this notwithstanding the great increase in mileage. Against this there was an increase of £4,500 in the general expenses. The Directors could assure the shareholders that this expense had been unavoidable, but there were reasons why it was not desirable to explain the matter further. Their relations with the Post Office continued in the same undesirable condition. Since the commencement of the business the Company had sent the cotton report to their subscribers, and now the Postmaster-General had forbidden this, and under penalty of losing their licence they had to submit.

Mr. HOFFGAARD, in seconding the motion, asked if any move had been made by the Company with a view to get communication with London.

The CHAIRMAN said the matter was a difficult one to deal with. Their own system did not extend beyond Lancashire and Cheshire, so that they could not initiate a demand for communication with London. In this matter they were in the hands of the parent company, and the parent company, he was sorry to say, had not shown itself very enterprising. The opinion of the meeting would be sent to them, and perhaps it would stir them up.

Mr. Alderman Thompson was re-elected a Director of the Company, and after a cordial vote of thanks to the Directors the proceedings terminated.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th inst. amounted to £3,870.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 26th, amounted to £2,672, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NOTES.

ELECTRIC LIGHT AT THE HAYMARKET THEATRE.—On the reopening of this theatre in a few days' time it will be lit by electricity.

SALE OF ELECTRIC PLANT.—In our advertising columns notice will be found of a forthcoming sale of the electric lighting plant now in use at the Liverpool Exhibition.

THE SOUTH FORELAND ELECTRIC LIGHTHOUSE.—The *Globe* of yesterday (Thursday) evening contains an interesting article by "An Amateur," describing a night in the South Foreland Electric Lighthouse.

LIGHTING OF COLLIERIES.—Mr. Ellis Lever, writing to *The Times* on the Exeter disaster, mentions that he has just heard of an order being given for 2,000 electric safety lamps for a South Wales colliery.

FINSBURY TECHNICAL COLLEGE.—We would call the attention of our readers to the notice in another column with regard to the winter session of the day and evening classes at the Finsbury Technical College.

TELEPHONE LICENSE ISSUED.—We are informed that the Postmaster-General has granted a license to the Equitable Telephone Association authorising them to establish telephone exchanges in the United Kingdom.

OUR COLUMNS.—The pressure on our columns this week, owing to the British Association, compels us to leave over some interesting papers, including the continuation of our articles on "The Rise and Progress of Telephony in the United Kingdom," as well as some correspondence.

ST. PETERSBURG OIL LIGHTING EXHIBITION.—We are requested to state that the time for receiving applications for the electric light department of the forthcoming exhibition at St. Petersburg has been extended to the 27th September, and that exhibits will be received up to the 27th October.

"ELECTRICAL DISTRIBUTION BY ALTERNATING CURRENTS AND TRANSFORMERS."—We have received from Messrs. Alabaster, Gatehouse and Co. a copy of "Electrical Distribution by Alternating Currents and Transformers," by Mr. Rankin Kennedy, an interesting work which we shall shortly notice at greater length.

THE LIQUIDATION OF THE GÜLCHER COMPANY.—At a meeting of the committee of investigation appointed by the creditors of the Gülcher Company resolutions were adopted recommending that the liquidation be effected under the supervision of the High Court of Justice, and that Mr. W. C. Jackson be appointed as liquidator.

FALMOUTH.—The Royal Cornwall Polytechnic Society is holding an exhibition at Falmouth. Electrical apparatus is shown by Mr. W. H. Perrow, electrician, of Truro, and by the Electric Apparatus Company of London. On Friday Mr. J. M. Carr, of St. Austell, will lecture on the "Production and Transmission of Electric Energy."

THE WESTERN COUNTIES AND SOUTH WALES TELEPHONE SERVICE.—On Monday last the Western Counties and South Wales Telephone Company opened several public call rooms in Bristol and in Gloucester, which will be available for communication over the trunk lines of the system as well as for the local service. The charges for the more distant places amount to 9d. and 1s. for three minutes' conversation.

LIVERPOOL.—At the meeting of the Liverpool City Council on Wednesday, a long discussion took place upon a recommendation of the Health Committee to apply for Parliamentary powers to authorise the use of steam "or other mechanical power," on their tramway. The resolution was eventually carried. The Picton Library, after being lit for some while by electricity, is to revert to gas. Great opposition was raised in the council to this step.

PERSONAL.—Messrs. Muir, Mason and Coulson, the well known electrical engineers, of Glasgow, inform us that they have taken into partnership Mr. J. D. F. Andrews, who lately carried on business under the name of J. D. F. Andrews and Co. The inventions of Mr. Andrews, which have been successfully applied to upwards of forty steamships and numerous land installations, become the property of the firm, which will, however, remain unaltered in style and title.

THE ECLIPSE BATTERY.—A few days ago a number of members of Parliament and others were privileged to examine, in one of the committee rooms of the House, some specimens of the Eclipse primary battery. The lamp used is of 2½ candle-power, and is described as having a semi-metallic filament. The charge is said to last for 12 hours, at a cost of 1d. for renewal of the liquid. The promoters of this battery are evidently well up to their work and are determined to keep the ball rolling as long as possible.

THE LIGHTING OF THE GLASGOW UNDERGROUND RAILWAY.—We hear with regret that the arrangements for lighting the trains in the tunnels of the Glasgow Underground Railway have not been completely successful as carried out by Mr. Carswell. It appears that the rolling contact by which current is taken from the stationary conductor does not work very satisfactorily, and the lights are consequently often below candle-power. If, however, our information is ill-founded we should be glad of a correction.

SUBMARINE COAST DEFENCES.—An intimation has been received at Portsmouth that, in consequence of the decision of a committee which sat to consider the question of coast defences, a series of submarine mines and electric contact wires will be laid in the channels through which large ships of war would approach Spithead, and it is probable that the whole of the forts will be connected with the mainland by a telegraph cable. As regards the latter point it is simply astounding that this should not have been done long before.

DAMAGE CAUSED BY GAS LIGHTING IN THE HOUSES OF PARLIAMENT.—In the House of Commons, on Thursday, Mr. Plunket, in answer to Mr. C. Graham, said there was no doubt that the use of gas in the cloister used as a cloak room was doing a certain amount of damage to the stonework of the roof, and he agreed as to the advisability of substituting the electric light. Unfortunately there was the odious question of expense, and he had been for some time engaged in having estimates prepared, which he hoped soon to submit to the proper authorities.

"PROF. ROGERS, F.R.S."—We learn from some of the daily journals that amongst the papers read before the British Association in Section G were two by Prof. Rogers—one on a new current meter, and one on a system of underground mains. We are sorry to say that the representatives of this journal have been unable to learn anything further of these papers or even of their distinguished author. By some singular coincidence it happens, however, that on the same day Prof. George Forbes, F.R.S., read a couple of papers in the same section on the very same subjects. Prof. Forbes is evidently a very near relation of "Prof. Rogers."

ELECTRICITY OF CONTACT OF GASES WITH LIQUIDS.—Replying in *Nature* to the communication of Mr. Enright (which was quoted in our columns on Aug. 26th, p. 329). Prof. Oliver Lodge writes as follows:—"Will you allow me to ask Mr. Enright how he proved that the 'charge of the escaping hydrogen was positive' or negative, as the case may

Digitized by Google

be? That the escaping *spray* was electrified by friction, after the manner of the steam spray in Armstrong's old hydro-electric machine, is a natural explanation of these capricious effects; but that *gas* should be thus electrified, and that this electrification should have any relation whatever to the subject of 'atomic charge,' are propositions which strike one as improbable."

MESSRS. KING, MENDHAM AND CO.'S CATALOGUE.—Messrs. King, Mendham and Co., of Bristol, send us a copy of the latest issue of their price list and catalogue, a profusely illustrated book of some 150 pages. In it are described and illustrated some new forms of the well-known Wimshurst statical machines, of which they are the makers. Automatic gas lighting apparatus, electric alarms, telephones and pneumatic bells, besides experimental apparatus of nearly every description are here described. It is satisfactory also to note that the prices of chemical and physical apparatus show a decided tendency downwards. We may be permitted to congratulate the firm in question upon the energy and ability with which their business is carried on.

ELECTRIC LIGHTING IN THEATRES.—Mr. Augustus Harris raises an objection to electric lighting on the ground of possible heating of the wires. To him replies, very sensibly (in the columns of the *Daily News*), one who signs himself "Electrical Engineer," and who writes as follows:—"I must say Mr. Harris's reason for objecting to the electric light, 'because there is great danger in it should the wires get heated,' is just as reasonable as if he were to say, I object to the use of cranes to lift heavy weights because the chain might break. Chains do not break if they are made sufficiently strong for the weights they have to suspend, and electric light wires do not get heated if the cable be made sufficiently large for the current. In all modern installations, worked out under the highly serviceable insurance rules, safety fuses are provided, thereby making it absolutely impossible for a fire to occur through the use of the electric light if the rules in force are properly carried out under competent and responsible supervision."

THE PYRO-MAGNETIC DYNAMO.—We confess we do not quite know what to make of Edison's direct-heat-conversion-into-magneto-electric-energy machine. The difficulty that will immediately present itself to everyone is to understand how the decrease in the temperature of the iron during the fraction of a second in which it is screened from the hot air blast can possibly be sufficient to produce so marked a change in its magnetic permeability. The screen rotates at the rate of 200 revolutions per minute; it therefore appears that the hot air passes through the iron tube for about one-sixth of a second, and is screened off for an equal period. It is true that the tubes are made of very thin iron; but this cuts both ways, for the magnetic resistance will be greater and the electrical efficiency (owing to the increased periphery) less in proportion. We can only say—as Prof. Perry said the other day in discussing Forbes's meters at the British Association—that we cannot too much admire the courage and skill with which the inventor has attacked the problem upon lines on which success would to ordinary minds have appeared so hopeless. However, any modicum of success in the direction of the immediate conversion of heat into electric energy is of such enormous importance that we would fain believe in the reality of the achievement. Illustrations of the machine will be found in another column.

TELEPHONY IN THE TEES DISTRICT.—Owing to the large increase in the traffic on their lines the Northern District Telephone Company have recently provided entirely new switching apparatus, and also made great alteration in the working of their exchange system in this district. At Stockton and Darlington the new arrangements have been in operation for some weeks, but the principal part of the work, namely, that at Middlesbrough, was only completed within the last few days. This involved the alteration of about 160 wires, of which more than half had to be newly erected. In addition to this, all the switch-board arrangements had to be altered. The work had to be completed between the hours of 3 o'clock on Saturday and 9 o'clock on the Monday morning, so as not to interfere with the working of the subscribers' lines; and it is highly creditable to the engineer-in-charge (Mr. E. R. Widdicombe) and his staff that the whole of the work was carried out without a single hitch. The Trunk system of the company has recently been considerably extended, and communication can now be had from Middlesbrough, South Stockton, East and West Hartlepool, Sunderland, Newcastle, North and South Shields, Tyne Dock, Blyth, Durham, Bishop Auckland, and Darlington. There are also now two distinct routes from Newcastle to Middlesbrough, viz., *vid* Durham, Bishop Auckland and Darlington, and *vid* Sunderland and Hartlepool, so that it is almost impossible for communication to be entirely interrupted.

PROFESSOR SCHUSTER'S EXPERIMENTS.—In connection with the results announced by Prof. Schuster as to the difference of potential between a metal surface and a gas in contact therewith, it is interesting to note that in the year 1878 (*Proceedings* Royal Society, March 21), Profs. Ayrton and Perry wrote as follows:—"In fact we have good reason to believe that there is no great difference of potential between a metallic or liquid surface and the air in contact with it." These views were, however, attacked by Clerk-Maxwell in a letter to this journal (*Electrician*, April 26th, 1879), who, writing in his good-humoured, bantering way, said, "A statement like this, coming from men whose scientific energy is threatening to displace the centre of electrical development, and to carry it quite out of Europe and America to a point much nearer to Japan, is worthy of all attention, even without an explicit statement of their 'good reason.'" And Maxwell went on to show the difficulty of reconciling this view with the well-known experiment of Mr. J. Brown on the contact potential of iron and copper in an atmosphere of hydrogen-sulphide. Shortly after, and no doubt in part in consequence of this argument, Ayrton and Perry seem to have abandoned the position they had taken up. For the benefit of those of our readers who may have missed Prof. Schuster's experiments, we may note that they show very strong reason for believing that "there cannot be a finite difference of potential between a gas and a metal in contact greater than one-quarter of a volt."

SIR WILLIAM GROVE.—The announcement of the retirement of Sir William Grove from the judicial bench affords a welcome opportunity for a brief recapitulation of the leading facts in the scientific career of one who has afforded a singular example of eminence in such apparently divergent paths. The musty, crabbed ways of legal lore might be supposed to have little attraction for a mind capable of the broad generalisation which characterises Sir Wm. Grove's most important contributions to science. Yet the Law was his first love, and to its study he returned with unabated ardour after nearly 20 years' devotion to science. In 1835, while reading for the bar, Mr. Grove (as he then was) was attacked by a slight illness which caused him to lay aside his law books and seek recreation in science. The early result was the discovery of the nitric acid battery, which for many years remained the most powerful source of dynamic electricity, and which we have the authority of Prof. Forbes for asserting, remains (without Eclipse)

Digitized by Google

about the very best primary battery for electric lighting to the present day. From 1840 to 1847 he occupied with distinction the chair of Faraday as Professor of Natural Philosophy at the Royal Institution, and during this period he wrote his great work "On the Correlation of the Physical Forces." In 1866 he was chosen President of the British Association, which sat that year at Nottingham. His presidential address on the continuity of natural phenomena ranks amongst the most famous of the series. Sir William is a member of the council of the Royal Society, and has received numerous distinctions from foreign academies. In 1853 he "took silk," led the South Wales and Chester circuits, and eventually rose to the Bench, of which he has since been one of the most distinguished ornaments.

THE "SPECIMEN GALLERY" AT THE BRITISH ASSOCIATION. In the "Specimen Gallery" set apart at Owens College for the reception of exhibits in connection with the British Association meeting, the principal interest for electricians centred in the new electric light measuring instruments of Sir William Thomson. These instruments were described and illustrated in this journal in the month of May. There were now exhibited a direct-reading vertical-scale voltmeter, a marine voltmeter, and a standard electric balance. Mr. Killingworth Hedges exhibited several cells of the Phœnix zinc-lead secondary battery, which were used for lighting some small lamps. Messrs. Glover and Co. showed a complete set of samples of the insulated cables which they had manufactured specially for the lighting of the Manchester Exhibition. Some specimens of soldered joints in large cables were shown, and side by side with these there was an instructive display of "how not to do it," consisting of a large number of faulty joints which had been cut out of cables of all sorts and sizes, and had been in actual use in electric lighting installations. The principal faults displayed by these joints were (1) lack of sufficient length—that is, the overlapping and twisted ends were generally too short to give sufficient area of contact; (2) neglect of the use of binding wire, which is very necessary in case of joining strands of large sized wire; and (3) imperfect soldering. In the latter case it was often evident that the joint had been made with the wire already in position, and consequently while one side of the wire had been perfectly coated with solder, the inner or lower side had almost entirely escaped. In joining heavy cables it is almost impossible to make a good job unless there be sufficient slack to get all round the joint. This is a point which should be carefully looked at in wiring.

THE LIGHTING OF THE GLASGOW BAZAAR AND CITY HALL.—At a meeting of the Glasgow Town Council a discussion took place upon the report of the committee which has recommended the lighting of the Bazaar and City Hall by arc light. The estimated annual expenditure was not to exceed the present cost of gas lighting, which amounted to £500 per annum. Mr. Brysom had prepared an estimate for the first cost of plant, which he put at £1,800. Mr. Simons opposed the recommendation of the committee on the ground that their proposals were of too vague a character. He also denied that the present cost of gas lighting amounted to £500 a year; from figures supplied by the gas office he found that it had been less than £300 for several years past. The first idea of using the electric light arose when it was under contemplation to light the City Hall, the Bazaar, and the new municipal buildings all from one central station. Circumstances had now altered, and the entire scheme had been changed. So far as he knew, no public building so large as the City Hall had been lighted with the arc light. Where electric lighting had been adopted it was by means of incandescent lamps. Ultimately, an amendment, moved by Bailie Macfarlane and carried by a majority of one vote, was adopted in the following terms:—"That it be remitted back to the committee to submit a statement of the cost of the plant and annual expense of the electric light, and, further, the relative cost of gas lighting by the modern and improved system." With regard to Mr. Simons' implied preference for incandescent lighting, no doubt there is much to be said upon his side, but we have never before heard it suggested that a building was too large to be lit by arc lamps. Mr. Simons doubts whether any building so large as the Glasgow City Hall has ever been lit by arcs. Well, to mention only one example, there is the Olympia Hall, at Kensington. Is the Glasgow Hall so very much bigger?

PRECAUTIONS AGAINST FIRE IN THE THÉÂTRE COMÉDIE FRANÇAISE.—At the present moment, when the appalling catastrophe at Exeter has once more peremptorily called attention to the urgent necessity for reform in the arrangements of our theatres, it will be opportune to describe a device which has just been brought into use at the Comédie Française, and which, had it been available at Exeter, would doubtless have been the means of mitigating, if not of entirely preventing, the worst features of the catastrophe. It is universally admitted that the means of securing the maximum degree of safety in theatres are chiefly:—(1) Proper structural arrangements; (2) Electric lighting; (3) The provision of an iron curtain completely separating the stage from the auditorium. The Comédie Française is at present only partially lit by electricity; but the work of extending the installation is now in active progress. It is, however, in the matter of the arrangements for manipulating the iron curtain that electrical appliances have been called upon to solve some of the chief difficulties hitherto encountered. These difficulties have arisen from the fact that the raising and lowering of the curtain has hitherto been a slow and somewhat difficult operation, and fears have been expressed that at the critical moment the manœuvre would fail to come off. The arrangement in force at the Comédie Française, which was devised by M. Edoux, provides hydraulic power for working the curtain, and matters are so arranged that the descent is effected by merely closing an electric contact; push buttons are consequently provided in various parts of the house, so that on the outbreak of a fire the very first duty on the part of the discoverer would be to lower the curtain. Moreover, to ensure that the whole of the appliances shall be maintained continually in readiness for instant use, the front of the curtain itself is painted as a "drop-scene," and the descent is effected every evening during each *entr'acte*. The time of descent is only very little longer than with a curtain of the ordinary description. The arrangement appears to be in every respect a desirable and successful one, and its first application at the theatre in question was greeted with a storm of applause.

EDISON'S MAGNETIC WHEATSTONE BRIDGE.—In another column will be found a description of a magnetic balance devised by Edison on the lines of the Wheatstone bridge. Since Kapp set the example of considering magnetic problems as analogous to the corresponding electrical problems under the added condition of a conducting medium, it has been evident that certain magnetic questions might be solved in this way, at least to a first degree of approximation. A little ingenuity would, for instance, probably discover methods of determining the magneto-motive force of a permanent magnet in terms of an electro-magnet with a given number of ampere turns after the analogue of Poggendorff's (or some more suitable), method of determining E.M.F., and similarly with internal and external magnetic resistance and so on. But as the result

Digitized by Google

would in general be capable only of about the same degree of approximation as would be obtained if the electric apparatus were plunged into a saline solution, it is scarcely reasonable to expect results of any great value. In making these observations we do not mean to imply that Edison's bridge is not fully entitled to a very respectful consideration. It will, however, probably be the general opinion that the arrangement is less convenient and certainly not more accurate than other well-known methods of determining the magnetic qualities of iron. A great difficulty in the use of the instrument would arise from the fact that the proportion of "leakage lines" will be upset when the bars to be compared are not of the same dimensions, or when their end contacts are not equally good, or when they are not of the same magnetic quality throughout. We should, however, much like to see some comparative test carried out upon a set of iron bars, first with Edison's bridge, and afterwards by one (or more) of the methods in ordinary use. As to the latter, it may be worth noting that one of the leading firms in this country has for many years employed the somewhat unorthodox method of testing the relative magnetic qualities of different samples of iron by their relative lifting power. Under proper precautions it is found that this method yields results which are perfectly concordant with those obtained by the use of Hughes's balance.

SCIENTICULISSIMUS AMERICANOS.—In America—as elsewhere—there are two kinds of "electricians," those who do the work and those who do the talking. The former variety happily far outnumbers the latter, and whatever may be their presumed theoretical shortcomings they are entitled to, and have always received from us, the substantial credit which is due to substantial success. For the latter variety we confess, as a rule, to have less sympathy. A story is told of one gentleman—whose name, by the way, is dignified by a prefix held in high repute on this side of the water, though we do not suppose that the title is of English origin—that at the time when Edison was known to be seeking to perfect the original platinum filament glow lamp the hero of the tale heard of the success which Pictet and Cailletet had achieved in solidifying hydrogen. With generous ardour, and in all good faith, he at once telegraphed to Edison suggesting that solid hydrogen would most probably prove to be the very thing he wanted for lamp filaments. This conception of a red hot hydrogen filament in a high vacuum will, we are sure, be admitted to be one of the most suggestive ideas that has ever been placed before the scientific world. The story is, moreover, easier to believe after reading some remarks made by the same individual in a discussion on Mr. Reckenzaun's paper on "Storage Cells" at the recent meeting of the American Electric Light Association. Mr. Reckenzaun was asked what was the rate of loss of energy in a battery when standing idle, and having replied to the question the meeting was further enlightened by the following learned and brilliant observations from the individual referred to:—"That result is exceedingly interesting, because it suggests something that was done by Faraday in determining the length of time that would elapse before a vacuum would be absolutely destroyed. It was there determined that it would take about one year for a Torricellian vacuum to disappear; so we have this action really verifying that. It is possible to keep it charged in that way for two years, you say, and still allow of some residual charge." The notion that the rate of loss of charge of a storage cell is intimately connected with the rate of leakage into a Torricellian vacuum is, again, one of those things which no ordinary mind can compass. But in the wildest vagaries of this scientific genius (of which, by-the-bye, we have several further specimens at hand) there is invariably a tone of geniality and good faith which leads us to esteem the individual even when we can only smile at the science. Occasionally we come across specimens, apparently belonging to the same species, of which the same remark cannot honestly be made.

THE EFFECT OF HEAT ON MAGNETISM.—In the September number of the *Phil. Mag.*, Mr. Herbert Tomlinson continues his account of researches on the physical properties of iron. He has now investigated the very interesting question whether the phenomenon of "recalescence" is or is not associated with the sudden loss of magnetic power which iron undergoes at a certain temperature. The investigation, therefore, comes very opportunely at a time when Edison is attempting to utilise the latter phenomena for industrial purposes. It may be as well to give in a few words the history of the subject. In the year 1869, Mr. Gore brought before the Royal Society an experiment which showed that when iron had been raised to a bright red heat, its contraction on cooling did not proceed uniformly, but at a certain temperature it suddenly and momentarily expanded. In September, 1873, Prof. Barrett extended the observation by showing that the momentary expansion was accompanied by a momentary flash into more vivid redness, and further, that the effect was not obtained unless the iron was previously raised to a temperature considerably higher than that at which the visible effect takes place. The experiment can easily be made with a Bunsen burner and a sewing needle. Prof. Barrett was of opinion that this phenomena—which he called "recalescence"—was associated with the loss or gain of magnetic properties. If this were true it would evidently tell seriously against the pyro-magnetic dynamo. Mr. Tomlinson, working with more elaborate means of research, has arrived at the conclusion that "it by no means follows that the phenomenon of recalescence occurs with *every* specimen of iron at the critical temperature at which iron loses its magnetic properties;" and remarks that he has sometimes noticed "*more than one* evident accession of heat during the same cooling." The important observation was made that in very soft iron wire molecular disturbance (evinced by change of volume) occurs at a much higher temperature on cooling than with harder specimens, and recalescence does not then manifest itself. We are not aware that any observations have been made as to the difference between hard and soft iron (or steel) in respect of the temperatures at which their magnetic properties are lost. Mr. Tomlinson is silent upon this point. The conclusions arrived at are thus summarised at the end of the paper: (1) There are two distinctly marked critical temperatures for iron; the lower somewhere about dull red, and the higher somewhere about bright red. (2) At the former of these critical temperatures the iron begins suddenly to lose its magnetic properties if it is being heated, and to gain them if it is being cooled. (3) At or *near* the latter critical temperature the iron, on being heated, if under the slightest torsional, longitudinal, or flexural stress or strain, begins to exhibit a remarkably sudden change. If the metal be under stress, the sudden change resembles that which would result from a sudden increase of elasticity. If the metal be permanently strained, there is a sudden increase in the amount of the strain. (4) When the iron is cooling a sudden change, but opposite in direction to that which occurs on heating, takes place. The temperature at which the sudden change takes place is, for very well annealed iron, nearly the same as that at which the change takes place on heating. If, however, the wire be not annealed, the change may be delayed by the so-called coercitive force of the metal until the lower critical temperature is reached. When the change is so delayed, the phenomenon of recalescence occurs.

THE SAFETY OF ALTERNATING CURRENTS.—If half of what we hear on this subject from America is true, it will be proper in future to speak of the safety rather than the danger of alternating currents. Prof. Houston has already told us how he has several times taken shocks of 1,800 or 2,000 volts (alternating) and felt little the worse. Now we have Mr. Smith, of Alleghany City, telling a long story about a lineman who got hold of a wire under a thousand volts and was unable to leave go until rescued after the lapse of *four* minutes. "By the time the ambulance got there he was sitting up and refused to go in the ambulance, and also refused to go to the doctor, seeming to be very much disgusted to think that an old man like himself should not be able to stand a thousand volts. His hand was pretty badly burned, but the next day he expressed himself as being perfectly well and able to go to work. He said he felt no particular pain when he first got hold of the wire, and was perfectly conscious for the first two minutes, but was unable to call out for assistance or to let the wire go; after that he simply forgot everything." This seems to us to be a highly remarkable case, which should be noted for future reference. On points of manipulation Mr. Smith, of Alleghany City, was equally instructive. "We have satisfied ourselves," he said, "that for alternating current conductors, if we can get a good metallic covering, it is about as good as anything that is to be had. In some parts of the streets we found it difficult to lay the wooden boxes, and we used iron pipes through which we pulled the cables and filled the pipes with pitch to prevent the average Irishman from driving his pick through them. We have not had the slightest trouble from loss of current or anything else. Yet our men handle those cables with perfect impunity. I understood that some experiments had been made by the Westinghouse Company with regard to insulation. I made some inquiries of them, and their answer was that we could use any kind of cable that we wanted to as long as the covering was good; but for practical reasons they should recommend to us in this particular instance a lead-covered cable, having both conductors in one lead covering. The question was raised as to whether our men would not be liable to get shocks from the covering of the converters if they were not grounded. We tried it and found no effect whatever. I have had no experience with a long conduit of iron. In the case of some telephone lines we found that if we crossed the wires every fourth or fifth pole we had no effect whatever from the current. In one case there was a double service of 7in. apart. We have had no trouble. There is a continuous musical note, which, however, is much less annoying than the buzzing from the ordinary machine. This crossing of the wires was done by us because they happened to be our wires. Of course we think that telephone companies ought to cross their wires themselves. Another thing: On these machines there is so little wear on the armature that the discharge is not so heavy. [Here we do not quite follow Mr. Smith.] The instant you break the circuit you are safe. There is so little shock that it does not amount to anything. Our linemen do our splicing without the slightest difficulty. We never think of shutting down the machines for them to splice up. Sometimes a man will say, 'It has been pretty hot up there to-day.' But they never complain of having any real trouble. They say that they would rather splice a 1,000-volt alternating wire than one in a 60-light Brush machine."

"LUMINOID" INCANDESCENT LAMPS.—A new incandescent lamp, called the Mace or "luminoid" lamp, has been introduced by the Vitrite and Luminoid Company in America. According to the *Western Electrician* Mr. Walter T. Goolden, M.A., F.C.S., reports that after a photometrical and electrical examination, conducted under his superintendence, of various samples of luminoid lamps submitted to him during the past six months, and after witnessing and examining the process of manufacture, he had formed a favourable opinion of the merits of the lamp on the following points:—1. Constancy of illuminating power throughout its life. 2. Durability under current. 3. Strength and elasticity. 4. Facility and cheapness of manufacture. In regard to the first point, he cites the following instances in support of his opinion that the lamp is superior to any in the market: "November 1st, 1886, two lamps were examined, marked 70 volts 20 candle-power. These had been running for over 1,500 hours at 70 volts, the volts being measured by a Cardew voltmeter, for whose correctness I am able to vouch. The test showed that at 70 volts they each took an average current of ·96 ampere, and gave 22 candles. Presumably, therefore, they had not lost candle-power by their long run, their efficiency at this pressure being 3·1 watts per candle. On the same day a batch of lamps were tested by me previous to running. They were then run for 912 hours, and again tested, the results being given in the appended table. The lamps were marked 45 volts 16 candle-power, and they were in both cases tested at 16 candle-power:—

Distinguishing Mark.	Before Running.		After Running.	
	Volts.	Amperes.	Volts.	Amperes.
1	44·0	1·32	44·5	1·36
2	43·0	1·31	43·0	1·30
6	45·2	1·31	45·0	1·25
7	46·0	1·35	45·0	1·34
8	45·5	1·38	45·5	1·30
Average	44·7	1·33	44·4	1·31
	Watts per candle 3·7.		Watts per candle 3·6.	

"Thus the lamps show no falling off in candle-power or efficiency after a long run, which would admittedly have reduced the light of the lamps of the best English makers by from 25 to 50 per cent. With regard to the durability of these lamps, while it is impossible to speak absolutely, from the absence of specific evidence, I may point out that the above named tests certainly tend in this direction, and that from what I know of the constitution of the filament, I may predict with considerable confidence that it will prove very superior in this respect to a carbon filament pure and simple. The filaments are remarkable strong and elastic, several of the lamps which I have seen having come from America in the ordinary post, without accident or damage to any of the filaments. The filaments of these lamps also present very marked physical differences to those of ordinary carbon filaments, some of them sustaining a full current for some little time in the air—from two to three minutes—before giving out. The process of manufacture, which I have seen and studied, compares not unfavourably with known modern processes of lamp manufacture in point of quickness and expense. I may say that nearly all the luminoid lamps tested by me have shown signs of careless manufacture, the vacuum being usually very imperfect; and the lamps in other ways gave evidence of bad workmanship. It is certainly remarkable that under such conditions the new luminant should present such a marked superiority to lamps made with all the skill attained by English manufacturers."

ON COPPER WIRE.*

BY W. H. PREECE, F.R.S.

At the (1885) Aberdeen meeting, in Section A, I gave some results of the behaviour of copper wire between London and Newcastle, showing how remarkable is its mechanical strength when hard drawn and pure, and how it is virtually free from those effects of electro-magnetic inertia which tend to throttle the flow of electricity through iron wires. The success of that experiment has led to the erection of four copper wires all the way from London to Dublin, in connection with a new cable laid between Nevin in North Wales, and Newcastle, near Wicklow. The result has exceeded our most sanguine anticipations, and its influence on speed of working will be referred to in a succeeding paper.

The wire used for the Welsh line is No. 12½ B.W.G., ·097in. in diameter, or 97 mils., weighing 150lbs. per mile, and giving a specified resistance at 60deg. F. of 6·05 ohms per mile. Its breaking weight was specified to be 490lbs., which is equivalent to 29½ tons per square inch.

The total length of the line between London and Nevin is 270·8 miles, of which 17·34 miles are underground. The resistance per mile when erected was 5·695 ohms at 30deg. F.

The capacity per mile was ·01319 microfarad and insulation per mile at 30deg. F. 70 megohms.

The following table summarises the elements of the different copper wires used in the Post Office :—

HARD COPPER WIRE.

Weight per Statute Mile.			Approximate Equivalent Diameter.			Minimum Breaking Weight.	Minimum Number of Twists in 3 inches.	Maximum Resistance per mile at 60 degrees F.	Minimum Weight of each Coil of Wire.
Required Standard.	Minimum.	Maximum.	Standard.	Minimum.	Maximum.				
lbs.	lbs.	lbs.	mils.	mils.	mils.	lbs.		ohms.	lbs.
100	97½	102½	79	78	80	330	30	9·10	50
150	146¼	153¾	97	95½	98	490	25	6·05	50
200	195	205	112	110½	113¼	650	20	4·53	50

The wire is subject to very strict inspection. It is carefully gauged and tested for ductility and tensile strength. It is wrapped in six turns round its own diameter, unwrapped and again wrapped in the same way; and it must do this without breaking. A piece is then gripped by two vice at a distance from each other of 3in., one being fixed and the other slowly revolved until the wire breaks. The number of twists the wire withstands is shown by an ink mark put on the top of the 3-inch piece before the test commences and which forms, as the wire is twisted, a spiral on the wire whose number of convolutions are easily counted.

The test for tensile strength is made by the direct application of a stress slowly augmented until the wire breaks.

The following table gives a record of some recent tests made at the Oakamoor Works of Messrs. Bolton and Sons :—

No. of Test.	Diameter in Mils.	No. of Twists in 3″.	Wrapping and unwrapping round own diameter.						B.W. lbs.	Resistance per Mile at 60° F. in ohms.
			On.	Off.	On.	Off.	On.	Off.

Averages ...	97·5	32·16	6	6	6	6	...	...	*513·41	5·814

* N.B.—This equals 30·6 tons per square inch.

* Paper read before the British Association Meeting at Manchester, September, 1887.

It will be seen that the tests in all cases exceed the specification figures. The average resistance was 5·814ω per mile, and this, for 97·5 inch diameter, is equivalent to 98 per cent. of pure copper.

So much depends on the care and accuracy with which copper wire is erected that an entirely new mode of wiring or putting up the wire has been introduced. Hitherto it has been customary to regulate the sag of iron wires by reference to a dip of 24in. in 100 yards, and to vary this for different spans and different temperatures by reference to tables. But foremen were governed very much by rule of thumb and regulated simply by eye. This would never do for copper, so special dynamometers or draw vice have been designed and fitted with Salter's springs, properly graduated, and the wire is always regulated to the proper tension.

The following table shows the corresponding sags and stresses of iron and copper wires under varying temperatures. It is based on the present specification for each form of conductor, and is calculated to allow a factor of safety of 4 :—

TABLE SHOWING SAGS AND STRESSES WITH VARYING SPANS AND TEMPERATURES FOR IRON AND COPPER WIRES.

——		At 22° Fahr. Low Winter Temp. (Hard Frost.)		At 40° Fahr. Ordinary Winter Temp.		At 58° Fahr. Average Summer Temp.		At 76° Fahr. High Summer Temp.	
Description of Wire.	Span	Dip	Stress	Dip	Stress	Dip	Stress	Dip	Stress
	Yds.	ft. in.	lbs.	ft. in.	lbs.	ft. in.	lbs.	ft. in.	lbs.
*No. 7½ Iron	100	3 1⅞	270	3 9	227	4 3½	200	4 8⅞	180
	90	2 6⅝	270	3 1⅝	219	3 2⅝	190	4 0⅛	169

100lbs. hard drawn Copper, No. 14..	100	2 8	80	3 7	59	4 3⅞	49	4 11½	43

* Factor of safety of 4 at minimum temperature.

The minimum temperature is taken at 22deg. F. Ordinary winter temperature may be taken at 40deg., average summer temperature at 58deg., and the temperature of a hot day at 76deg.

These figures serve the same practical purpose as the use of thermometers, which, if placed in the sun, would not as a rule record the actual temperature of a wire in course of erection.

The stress, as measured by the new dynamometers, should in all cases correspond with that shown in the table for a given conductor and average span under the temperature prevailing during the erection of the wire. This stress will vary for different spans at the same temperature; but the figures opposite the average span for any given line and temperature are those employed in practice.

Sags and stresses for copper and iron wires do not vary in the same ratio under changes of temperature owing to copper having a higher coefficient of expansion than iron. With spans of less than 80 yards the difference is not so great as to render it unsafe to run iron and copper wires together, but as spans increase beyond this length some danger of contacts may arise, and a slight departure from the tabular results may then be permitted to obviate this difficulty. For example, in special instances the copper may be run with a greater dip or the iron with a lesser one. It is, however, better not to run copper and iron together on spans exceeding 80 yards.

In drawing up this table the following formulæ were employed :—

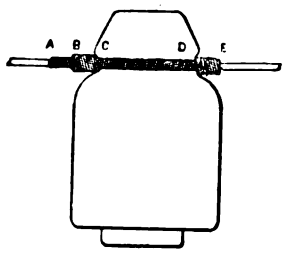
$$d = \frac{a^2 w}{8t}\,;\quad d = \sqrt{\frac{3a(s-a)}{8}}\,;\quad s = a + \frac{8d^2}{3a}\,;\quad t = \frac{a^2 w}{8d}\,;$$

where a = span, d = dip, t = stress at insulator, w = weight of unit length, and s = length of wire in span.

Digitized by Google

Coefficient of expansion for iron = ·0000123 per deg. C.
" " copper = ·0000172 " "
w for 400lbs. iron = ·075758 per foot.
" 150 " copper = 028409 " "
" 100 " " = ·018738 " "

The wire is bound to the insulator by finer copper wire, and a sample of the way this is done is shown on the table.



Two wires are whipped round the line wire from B to E, thence back to D; then from the *upper* side of the line wire they are taken round the neck of the insulator to the *under* side of the line wire at C, back over the first layer to B, and then taken on as a single layer to A.

The length of wire required for each binder is :—
For 150lbs. line wire .....52 inches.
For 100lbs. " .....40 "

The binding wire weighs 50lbs. per mile, and is No. 17½ B.W.G.

Copper wire requires very careful handling. Flaws, indentations, scratches, kinks, and similar injuries act very much in the same way as diamond scratches on glass. Special drums, fitted with breaks, have been designed and made so that the coils of wire may be *unwound* under tension, like a reel, to prevent the possibility of kinking, or putting unnecessary turns in the wire.

The joints are the ordinary Britannia joints, whipped with No. 20 tinned wire, chloride of zinc or Baker's fluid being used as a flux for soldering. It is only necessary to avoid the continued application of heat, for heat softens and weakens the wire; quick soldering is therefore essential.

Copper wire being practically free from electro-magnetic inertia or self-induction, its time constant, or the amount of retardation it exercises on the rate of flow of electricity, is simply the product of its capacity K, and resistance R.

K R for 400lb. iron is ..... ·2116 per mile,
and for 150lb. copper is ..... ·0786 "

But iron has electro-magnetic inertia, which still further retards the rate of working; and therefore the speed on a copper aerial line ought to be at least three times greater than that of an iron line.

This influence of self-induction is extremely difficult to explain. An analogy sometimes assists explanation, but it more often makes confusion worse confounded.

Supposing we had a water pipe of circular section, made of some material which was remarkably sensitive to cold, and which would contract in section along its whole length with the slightest motion of the water, and that the amount of this contraction varied with the rate of motion of the water, then when the water commenced to move, the circular section of the pipe would diminish in area, the flow of water would become checked, and the faster the water flowed the more the passage would become choked, therefore the less quantity of water which would be discharged in a given time. This is analogous to the effect of self-induction in a circuit conveying rapidly alternating currents of electricity; the whole passage becomes choked throughout its length, and less electricity is discharged in a given time. In the former case, it is as though the head driving the water through the pipe were diminished; in the latter case, it is as though an opposing E.M.F. were set up in the wire diminishing the value of the original driving power. In each case the effect may be said to be due to the creation of a spurious resistance to the motion set up by the motion itself. The effect of friction on the flow of fluids is by no means dissimilar to that of self-induction. Anyhow, this self-induction, or as it is better known in its general sense, *electro-magnetic inertia*, is a serious hindrance to rapid telegraphy and to long-distance speaking on telephones. It has now been practically eliminated from the line by the use of copper wire, and no other material should be used for telephones. The so-called Phosphor and Silico bronzes, when of high conductivity, are in reality very nearly pure copper, and may be classed with copper.

We are now erecting a new copper wire from London to Newcastle, another from Newcastle to Leith, and a third from London to Doncaster.

We have put up 350 tons of copper during the last three years.

DISCUSSION.

Sir FREDERICK BRAMWELL asked what was the variation in practice in the tension of the wire both in iron and copper with such ranges of temperature as were ordinarily or extraordinarily met with in this climate. He would also like to ask what was the objection to attaching the wires to a spring on the pole which would yield with a definite tension, which tension would not be much increased within the small range needed to maintain the catenary.

Mr. PREECE said that the ranges of stress in iron wire varied from 270lbs. in winter to 180 in summer, and the difference of dip or sag was from 3ft. 1in. in winter to 4ft. 8½in. in summer (per 100 yards). In copper the range of stress was between 120lb. in winter to 64 in summer, and the difference in dip given was from 2ft. 8in. in winter to 4ft. 11½in. in summer. With regard to the suggestion made, he thought it would be impracticable, because it would be essentially necessary to have a joint on every pole, and although a joint offered practically no resistance it was a thing to be avoided.

Sir FREDERICK BRAMWELL said that all he suggested was that there should be a piece of slack wire between one spring and another, and it seemed to him that if that were done a much more uniform stress would be attained than was the case at present. He thought it would be most desirable that Mr. Preece should turn his attention and that of the staff under him to the important question of hanging wires so that London might not be placed in the awkward position it was in last winter. There ought to be no difficulty in solving the problem.

Mr. RICHARDSON commented on the cheapness of copper, and said that this was a favourable time for substituting it for iron.

Major-General WEBBER asked whether Mr. Preece's experience had afforded him any results as to when the copper wire which was now used by the Post Office began to stretch so as to affect seriously the regulation of the wires, and whether any comparison had been made between copper and silicon bronze wire in that respect. The subject raised by Sir F. Bramwell had occurred to telegraph engineers twenty years ago, and he (the speaker) fully endorsed what Mr. Preece said from the construction point of view.

Prof. PERRY thought that General Webber did not quite apprehend the way in which Sir Frederick Bramwell intended the spring attachment to be made. The suggestion was to employ a slack wire between two gripping springs without a break. He thought there was sufficient genius among electrical and telegraph-engineers to have evolved that method long ago had there not been some practical objections. Prof. Perry next referred to a method of testing the tension of a wire by counting the number of vibrations it gave under different tensile conditions, and said that it was one which gave the most accurate results.

Mr. PREECE said it was a very difficult thing to answer a practical suggestion like that made by Sir Frederick Bramwell. He was bound to admit that it was a suggestion that deserved serious consideration. But Sir Frederick's argument seemed to be based principally on the fact that the wires, especially in the earlier part of the year, were lying about broken for weeks in London. He might say that the trouble arising from snowstorms and tempestuous weather did not affect the Post Office system, with which he (the speaker) was immediately connected, for in all large cities, without exception, their wires were placed underground, and in large cities that was the only practical and proper way to deal with the question of danger from overhead wires, if there was any danger. For the forty years during which telegraph wires had been overhead there had been only two instances of loss of life (which he specified), and those two were solely due to carelessness. The cry of danger that was raised from overhead wires was all moonshine. It was formerly the practice of the linemen, by means of their winders, to tighten the wire at every quarter of a mile in summer, and to slacken it in winter; but this was found to be an unnecessary trouble. If it were simply a case of snow adhering to the wire no harm would arise, for the wire would be strong enough to bear the weight of the snow; but when the snow was accompanied by a gale of wind, blowing at a pressure of 15lb. to 20lb. per square foot, the tension of the wire became so great that it would carry away Sir Frederick Bramwell's tension regulators, posts, and everything. During the gale they experienced in the early part of the year, when the snow, wind, and frost conspired together, poles of 12in. diameter that could bear he could not say how many tons per square inch of pressure were swept down like matches, and his experience when those snowstorms came (which they only did, fortunately, once in ten years) was that there was no practical device ever suggested that would enable them to get over the difficulty. In reply to General Webber, he might say that the stretch of copper wire was very small indeed, rarely, in fact, exceeding ½ per cent. The wire almost invariably broke before it was stretched to that extent. He drew no distinction between copper and silicon bronze. All the wires that had been supplied as silicon bronze had turned out to be copper, and copper it virtually was. He regarded Prof. Perry's suggestion, that they should see how far his method of vibrations would apply to light wires, as a very good one. He

Digitized by Google

went over the particular Welsh lines referred to in his paper with the express object of seeing what influence the changes of temperature had upon the stresses of the wire and the sags, and at a great many different spots he inserted in the line wire a dynamometer, so that they had the direct pull of the wires measured, and he found the results to be eminently satisfactory.

ON THE PRODUCTION OF A CONSTANT CURRENT WITH VARYING ELECTROMOTIVE FORCE FROM A DYNAMO.*

BY A. P. TROTTER, M.A.

Nearly all the earliest dynamos made for practical work were intended to give a constant current for arc lights in series. Few attempts were made to extinguish separate lights, partly on account of the light being generally required for outdoor work and partly by reason of the contentment with which Americans accept a successful notion without demanding the refinements which are expected in this country.

The problem is to vary the volts when the external resistance is altered, so that the current may be kept constant.

The best known methods are those of Thomson-Houston, Maxim-Weston, and Hochhausen. These rock the brushes on the commutator by means of automatic arrangements on which considerable ingenuity has been expended, and the results, so far as they are applied to arc lighting, are satisfactory.

The armatures of dynamos for series arc lighting are, for several well known reasons, made with less iron and with more wire than those of machines used for other purposes, and a high resistance both of armature and field coils, together with a considerable amount of induction and heating, are, as a rule, inseparable from dynamos for arc lights, and although such proportions preclude the possibility of a high efficiency in the dynamo, it is generally considered that these losses are made up for by the economy of a small conductor and the simplicity of working with a uniform current. With such armatures, the volts may be reduced by rocking the brushes, and if the proportions of iron and wire are correct, this will produce hardly any sparking or additional heating.

A constant current is required for several other purposes than for arc lamps, *e.g.*, the Bernstein system of low-volt lamps in series, certain applications of motors, and for electro-deposition with baths in series. For such purposes there would be no advantage in using a small quantity of iron in the armature, unless to enable the brushes to be rocked, an advantage which would be dearly bought by the low efficiency.

Several attempts have been made to produce a constant current by compound winding, but they do not appear to have met with success. In such a machine the characteristic should be a vertical straight line, but practically it is merely the usual rounded extremity of a shunt characteristic, and the current is therefore only approximately constant. The winding is nearly all shunt, with a few turns of series coils, which are of little use, since it is never necessary to short-circuit the machine, the minimum work being one arc lamp or nothing. The difficulties of insulating, and the expense of winding the fine wire required for high volts would be serious obstacles to compound winding for constant current, even if a fairly constant current could be produced. The method may be worth using for three or four arcs.

Another method has been employed in the Brush system, viz., shunting a portion of the exciting current of the magnets, and thus weakening the strength of the field. It appears that this can be carried farther with a Brush dynamo than with more modern machines. The difficulty is, that if the excitation of the field be reduced to such an extent that its magnetic resistance approaches its initial value, or, considering the saturation curve—when the working point approaches the nearly straight part of the commencement of the curve—the volts become unstable, and the current is liable to drop. If the reduction were very gradual, and the speed perfectly uniform, it might be possible to reduce the volts to a low point if the machine were working on a dead resistance; but with arc lamps it would be impossible, and even with a resistance it is found that from small fluctuations of speed or some other cause the instability is always present.

With an automatic regulator to control the resistances used as a shunt to the field the difficulty increases, for it would attempt to correct a small accidental drop of volts by increasing the strength of the field, and serious hunting would ensue. Arc light dynamos of modern design, by several of the leading dynamo builders, have been successfully controlled by the automatic regulator, to cut down to half the full load with a simple shunt. Instability sometimes is present in shunt wound dynamos used at one time for charging cells, and at another, at lower volts, for running glow lamps direct, the reduction being effected by adding a resistance to the shunt. If such a machine be compound wound, the instability would only be noticed on a small load.

In discussing means for remedying this difficulty, Mr. H. W. Ravenshaw, senior electrician to the firm of Goolden and Trotter, suggested that the reduction might be effected *while the field-magnets were saturated* to the usual point, by diverting the lines of force from their usual path from pole-piece to pole-piece through the armature, by offering a path of lower magnetic resistance. It was proposed to do this by employing a movable mass of iron, which had better be termed a "keeper" (in order to avoid the word armature). The mass of such a keeper would be considerable, and in the course of discussing the mechanical problem of moving it by means of an automatic regulator, the writer proposed, instead of moving it, to neutralise its effect by passing a current round it, thus obstructing the passage of the lines of force through it, and rendering it practically inert, non-magnetic, or altogether abolished.

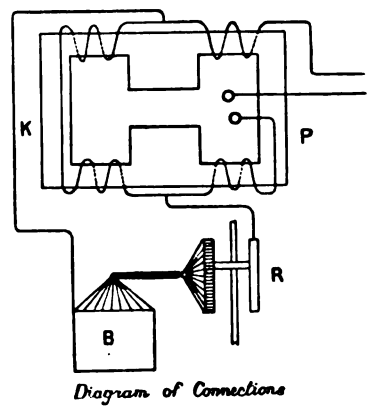


FIG 1.—K Keeper. P Terminals.

The first practical experiment was carried out a few minutes after the invention of the method, with an ordinary series-wound arc lighter of the Gramme type with Goolden-Trotter modifications, and the results were very satisfactory. The double magnet type of dynamo is very suitable for this purpose, for one half of the machine may be constantly magnetised to the desired point of saturation, while the other half acts as a keeper. The former may be called the constantly magnetised limb, and the latter the keeper. They are similarly wound with exciting coils. If when the constantly magnetised limb is fully excited by the usual current through its coils, and no current is passed through those of the keeper, the latter will act as a magnetic shunt, and nearly all the lines of force will pass round and round in a closed circuit of iron. Little or no polarity will be found at the pole-pieces, and there will be a minimum effect on the armature. By allowing a weak current to pass round the keeper the diversion of the lines of force through it will be partially obstructed, and the rest will take their usual path through the armature. With a certain strength of current this obstruction will be complete, and the magnetic effect is the same as though the keeper had been entirely removed from the dynamo. The strength of the field, and its action on the armature is the same as though the dynamo were provided with one magnet only. If now the current through the coils on the keeper be increased beyond this neutral point it will assist the permanent

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

magnet; the lines of force in the former will be reversed, and finally when the whole current passes round it, the volts are at the maximum, and the dynamo works as an ordinary series-wound machine.

It was soon found in practice that, owing to the complete magnetic circuit formed by the pair of magnets, the changes in the strength of the field were somewhat sluggish. This was easily remedied by making a gap in the magnetic circuit, by boring out the yoke or side where the magnet bars pass through and bushing them with brass, using brass washers also on the ends of the bars and under the nuts. Experiments have yet to be tried to ascertain the minimum dimensions of this non-magnetic gap. It is important that it should not be too great, not so much on account of the greater expenditure of energy required for the magnet coils, as for the reason that if the magnetic resistance be high it will be impossible to reduce the volts of the machine to a low point. It is evident that the method consists in shunting the useful magnetic field, and the minimum effect can only be obtained by a magnetic short circuit, and the presence of the gap, if of large dimensions, prevents short-circuiting or diversion from being complete. The difference of magnetic potential at the pole-pieces will be practically as great as that at the gap when the keeper is neutral. In the second experiment, in which the gap was introduced, the volts of the machine could not be reduced, for this reason, to less than about one half. It is probable that they can be reduced to from 90 to 95 per cent. without causing sluggish changes.

A practical application has been made of this method for the purpose of running Bernstein glow-lamps arranged in series, and a dynamo controlled on this system by an automatic regulator enables the lamps to be extinguished by short-circuiting. For this purpose an armature of high efficiency can be used, and the current of ten amperes can be maintained constant within 0·2 ampere.

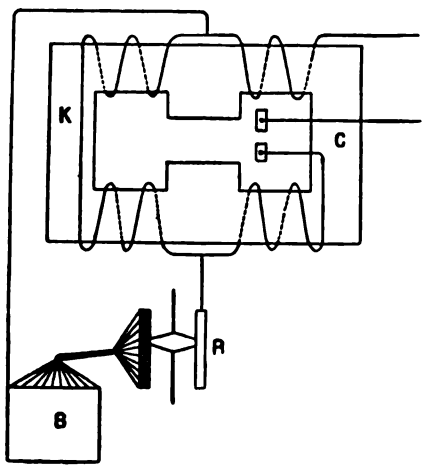

FIG. 2.

C Constantly Magnetised Limb. K Keeper.
B Resistance Box. R Regulator.

It is probable that with this system, armatures of considerably higher efficiency can be used for arc lights, especially as such a nicety of regulation is not required. Experiments have not been carried out far in this direction yet. The system is applicable to dynamos used at one time for charging and at another for running direct, or for any other purpose in which it is desired to reduce the intensity of the field to or beyond such a point as will endanger the stability of the magnetisation.

The practical control of the current in the coils of the keeper has been effected by the mechanical regulator, which may now be said to be a well known appliance. The rheostat is connected to a set of resistances calculated for the particular dynamo.

Curves Figs. 3 and 4 were shown, explanatory of these experiments.

The calculations have been worked out by Mr. Ll. B. Atkinson, and the following is an outline of the method which has been adopted:—

Take a series of values of μ, the number of lines per square inch of armature iron. From this number and the magnetic curve of the material a series of values of magnetic resistance are found. To these add the polar air space resistance, and hence determine the magnetic potential between the poles by multiplying the number of lines by the resistance. This magnetic potential must be equal to the total magnetising force (ampere turns) on the constantly magnetised limb, less the value of lines of force multiplied by the equivalent magnetic resistance, or in symbols:—

$$T_1 - \mu_1 a_1 r_1 = \text{magnetic potential},$$

where a_1 is the area of the limb. But T is fixed and μ_1 can be found. This gives the total lines coming to the poles, and these are equal to the lines through the armature + the lines of leakage between the poles + or − the lines through keeper. Having thus found the lines through the keeper, we find its magnetic resistance for those lines, and the ampere turns necessary are found by the equation

$$T_2 = \pm \mu_2 a_2 r_2 + \text{magnetic potential}.$$

Where T_1 and T_2 are ampere turns, a_1 and a_2 are areas, r_1 and r_2 magnetic resistances of the constantly magnetised limb and of the keeper respectively.

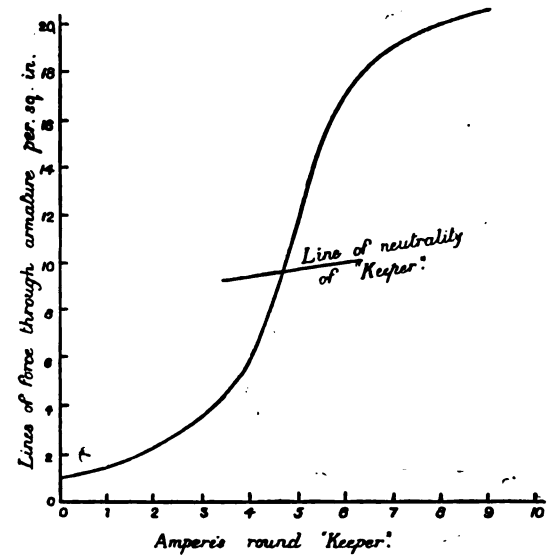

FIG. 3.

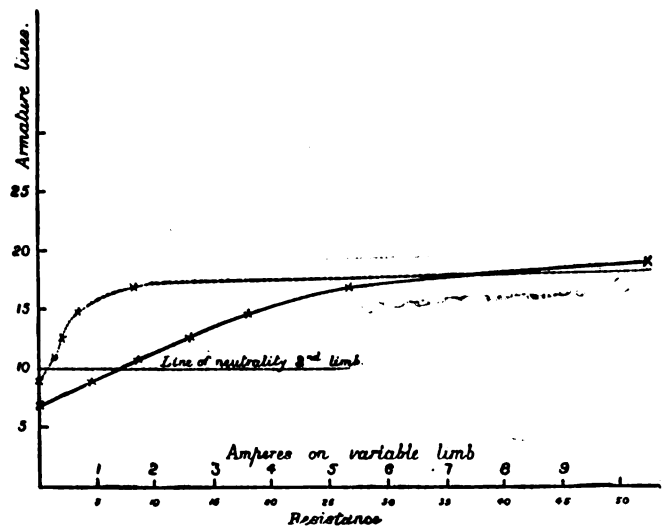

FIG. 4.

A curve is exhibited, showing how the number of (Kapp) lines of force through the armature is raised by altering the current in the coils of the keeper. It would need a keeper of perfect magnetic conductivity to totally short circuit the constantly magnetised limb.

THE EXETER THEATRE.

Under the weight of such an appalling disaster as that which has just visited the city of Exeter, and which has spread consternation throughout the length and breadth of the land, it requires no inconsiderable effort, both moral and mental, to approach the subject from the point of view which it is the duty of this journal to uphold. Nevertheless, we feel that it would be mistimed scrupulosity, and something little short of cowardice, to shrink from pointing the obvious moral of this deplorable accident through fear of seeming to seize the opportunity for what may be called improving the occasion. It was not in this spirit, as our readers will remember, that we commented on the fire at the Opera Comique at Paris; and when a more dreadful calamity has overtaken us at home we are still less disposed to yield to the temptation now. We have never thought it our policy to attack the gas interests on account of the accidents to which their system of lighting is liable; nor in any of our recent remarks on the lighting of places of public amusement have we blamed the management for not adopting a safer system. We frankly recognise the fact that Gas is in possession of the field; and it would be grossly unfair to lay the fault of a catastrophe due to the use of an old-established form of light upon the shoulders of anybody simply because they have not yet seen the necessity for adopting a safer but newer form.

Having said this much, we feel ourselves at liberty to comment freely upon the fatality at Exeter with a sole view to preventing a recurrence elsewhere, so far as any words of ours can tend to that object. The outbreak of the fire was almost identical with that at the Opera Comique, and the consequences differ only in respect to the structure of the building. In both places gas was the illuminant, and at both it was something in the flies that was ignited by the jets. At Exeter, we have it on the authority of the actor who was on the stage at the moment that he saw the gas battens on fire; and his surmise that one of the calico mediums which go over the cages surrounding the gas lights had caught fire is probably the correct one. In a moment after the flies were alight, and the drop scene, which had been promptly lowered to prevent the spread of the fire, was itself in flames, and fell on to the stage. Had it fallen the other way the occupants of stalls and pit might not have escaped as they did. By this time the whole of the upper machinery of the stage was in a blaze, the theatre itself enveloped in smoke, through which it was seen that the flames were spreading to the ceiling and roof. How quickly all this happened may be gathered from the fact that a gentleman in the stalls, who on the first alarm had rushed out into the streets, found when he got there that the flames were issuing from the windows on both sides of the building.

What followed it is needless for us to describe. Suffice it to say that in probably less than a quarter of an hour more than a hundred and fifty people were suffocated, burnt, or trampled to death. In respect to the latter, we may now recall what we said in our leader only six weeks ago. On the gallery staircase, the one sole outlet for the audience in the uppermost part of the house, there was the usual ticket barrier, which, as we urged at the time, ought always to be removed when the play has commenced. There was also, by a grim irony of fate, a patent fire extincteur, over which an eye witness—one of the very few who escaped from the gallery or upper circle, we are not sure which—tells us that he saw several people stumble. A block ensued, and we know the inevitable consequence. In the dress circle the outlet to the *foyer* was handy; and even the stall people were able to stumble up a few stairs, along a passage, and so to the vestibule and street. The extra exits from the pit were, as usual, closed; but happily the pressure of the crowd burst the doors off their hinges, and escaped for the most part with nothing worse than a few bruises. To the upper part of the building the chief fatality was confined; and this being the rule in such cases is an important fact to be borne in mind. It points to the general certainty that fires at theatres will originate on the stage, that the flames spread to the roof, and that the audience in the highest part of the building incur the greatest danger. It is precisely this part of the theatre which is most difficult to provide with adequate exits.

How long the gas remained alight on the gallery staircase we shall perhaps never learn; but probably not many minutes, as there was an explosion of gas on the stage before even the actors could get clear away. What we do know for certain is that gas was burning above the stage in close proximity to materials of the most inflammable kind. We also know that there was nothing uncommon or reprehensible in this arrangement, seeing that it has the sanction of custom to shield it from condemnation. None the less it is a bad custom, and one which ought to be amended without loss of time. It would be too much to expect that every theatrical manager will at once introduce the electric light into his stage fittings in the place of gas; but we do hope that many will do so, for it is impossible to suggest any light other than the electric that would be in all respects safer than gas. The electric light would be absolutely safe. Neither at Paris nor

Digitized by Google

at Exeter would there have been any conflagration had the electric light been employed; and of no other light that we are acquainted with can this be said with such perfect confidence—or, indeed, with any confidence at all. Arranged on the plan we described in the article to which we have already referred, and carried out by competent electrical engineers, the building would not only be safeguarded from the ordinary risk of fire but also from the consequences of panic arising from any cause whatever.

Emphasis is given to these reflections by the fact that the theatre at Exeter was a new one, constructed on the latest principles, and apparently provided with appliances and means of safety which are by no means universal even in metropolitan theatres. The outlets for pit, stalls and dress circle were fairly adequate; there was, as we have mentioned, a fire extincteur on the gallery staircase, and, better still, there was on the first tier a hose, which was actually brought into use without any delay; and, lastly, the curtain was lowered just when it ought to be. All these circumstances reflect great credit on the management and on the presence of mind displayed by its subordinates. These and the heroism of the rescuing parties outside deserve the warmest praise, none the less because they were only partially successful. Not quite 200 persons were in the gallery, yet more than half of them it is certain were killed. But for the precautions just mentioned the fatality might have been at least twice as great. There has been the usual talk about panic; but in this case there was no time for steadfastness or reflection. The conflagration was so sudden, so rapid, so overwhelming, that the only chance of life was in instant flight. We ourselves see no conclusive evidence of panic; at all events, all the dreadful consequences which we are now deploring were due to fire; and our last words on this point are that fires of this description need never occur if the prime source of danger were removed—a removal which modern science has now enabled us to accomplish with ease, economy, and certitude. The English papers are full of suggestions for affording means of escape when a fire breaks out; what we urge, and what is being urged unanimously by the Continental press commenting on the Exeter disaster, is that the cause of fire should be got rid of as it has been in most of the great theatres of France, Italy, Austria, and Germany.

RADIATION FROM DULL AND BRIGHT SURFACES AS AFFECTING INCANDESCENT LAMP CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to think that the practical conclusion as to the superior light-giving efficiency of the brilliant looking surface carbon over the dull-looking surface carbon has been tacitly recognised by most lamp makers for the past three or four years.

In the investigations of Mr. Mortimer Evans (Roy. Soc. *Proc.*, Vol. XL., 1886) and by Mr. Bottomley (*The Electrician*, September 2nd, 1887) it is stated that "the same" carbon "filament was treated in such ways as to alter the surface from dull to bright and back again," but they do not state whether either the actual surfaces (upon which radiation is directly dependent) or the surface densities were the same with both filaments; for without either of these measurements their conclusions are not warrantable. In fact, with a pure carbon a brilliant surface is inseparable from a dense surface, and from experiments I have made at different periods during the past two years I find that the light-giving efficiency is dependent in a great degree upon the surface density or degree of porosity.

I find it possible to commence with carbons of the same length and diameter, and to "flash" them in different ways to the same resistance, yet to have their diameter and surface areas quite different; which shows that in one case the surface of the carbon is more dense (less porous) than in the other.

A dull surface carbon prepared as above has a greater porosity, and, therefore, surface area, or has least surface density, and requires a greater amount of energy than the more dense or brilliant surface carbon to bring it to the same measured candle-power or apparent surface temperature.

(I say apparent surface temperature, as I think the points or hills on a dull surface carbon must cut off some of the light radiated from the hollows.)

A brilliant looking surface carbon prepared as above has the least surface area and greatest surface density.

From various experiments I have made, and from those I mention below, I find that the light-giving efficiency and emissivity of a carbon filament is not effected so much by the fact of the surface being dull or bright as it is by the actual density (porosity) of surface.

To prove the relation of light-giving efficiency of a carbon to its surface density, I took three carbons of the same length and diameter and "flashed" them in various ways, so that their final resistances, lengths, and diameters (but not necessarily actual surfaces) were the same.

The "flashing" was so arranged as to obtain carbons of three different structures; *i.e.*, the first carbon had a dense centre or core and a black exterior; the second carbon had an even texture throughout, with a smooth dark grey exterior, but not bright looking; the third carbon had a black porous interior or core, with a brilliant-looking and dense exterior.

The densities were determined by total weight in air and weight at different diameters, and when the carbons were examined under the microscope, the deposit of greatest density had the most brilliant appearance and took place at the highest temperature. These carbons were very long and thick, and were enclosed in glass globes, which were exhausted on the same pump to a high degree.

From the actual tests of these three carbons, it was conclusive that their light-giving efficiency was dependent upon the surface densities, which is a point not observed by Mr. Bottomley, or by Mr. Swinburne, when he mentions experiments he made on the emissivity of dull and bright carbons ("Incandescent Lamp Manufacture," No. XX., *The Electrician*).

Another point I observed from the above experiments was that for a given increase of energy the alteration of hot resistance of a carbon varies with its surface density, and it may be that this fact alone is the chief cause of the differences observed by Mr. Mortimer Evans and by Mr. Bottomley, and would explain why both the black-surfaced (more porous) carbon and platinum required a greater amount of energy than the brilliant surfaced carbon and platinum to bring them to the same measured candle-power.

I should like to be able to prove the effect of a brilliant-looking even surface carbon, and of a brilliant looking nodulous surface carbon, each of the same length, diameter, and resistance, but have not the opportunity at present.

From the observations I have made, I conclude that a pure carbon to possess the greatest light-giving efficiency and duration (other things being equal, vacua, &c.) should have the greatest possible density—that is to say, should be prepared at the highest possible temperatures, and if deposited from a gas or liquid the matter used should require the highest possible heat for its decomposition; also the carbon should have a brilliant and smooth surface.—Yours, &c.,

C. J. ROBERTSON, A.S.T.E.

THE D'HUMY WATER BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read a paragraph in the *Morning Post* of Thursday, August 23rd, 1887, which speaks very highly of Mr. P. D'Humy's primary and secondary batteries. Combined they appear, at very little cost, to give magnificent results; and also by simply turning a switch it is claimed that lights of various

Digitized by Google

candle power can be used on the same wire at the same time. It is no novelty to use primary batteries for storing electricity, and I have done so with the E.P.S. Company's small secondary cells, with very fair results. But I have not yet seen the combination perfected, and I should be very glad if some of your readers who have inspected Mr. D'Humy's method would give a practical description of it in your valuable paper.—Yours, &c., CHARLES PENRUDDOCKE.

THE GENERAL THEORY OF DYNAMO MACHINES.*

BY DR. E. HOPKINSON.

Using the term "dynamo" in the widest possible sense, including under it all machines for the conversion of mechanical forms of energy into electro-magnetic, and electro-magnetic into mechanical, there are certain characteristics common and essential to all types of such machines, whether they be known as magneto machines, alternate current machines, or continuous current machines, either compound, shunt, or series wound, and of the drum, ring, or disc type. It is therefore possible, up to a certain point, to construct a theory of dynamo machines which is perfectly general in its application. The object of the present paper is to trace briefly the outlines of such a theory, and to indicate how the consideration of specific types of machines can be developed therefrom, and in what direction research is required to elucidate some points still obscure. A dynamo consists essentially of two closed circuits or "tubes," in both of which there is a displacement of the nature of a flux dependent upon the relative motion of the two circuits. We may call one of these the "magnetic circuit," and the other the "electric circuit." Either or both of these may be in motion; but as we are concerned only with the relative motion of the two, we may for convenience (as, in fact, is usually the case) regard the magnetic circuit as fixed, or displaced only by the reaction of the electric circuit upon it, and consider the latter only as moving under external forces, whether electric or mechanical. The flux along the magnetic circuit is called the "magnetic induction," which is a vector or directed quantity, requiring for its definition reference to co-ordinate axes. It is subject to the fundamental condition known as the "solenoid condition," or "equation of continuity," which may be expressed in words "that the flux across all sections of the tube is the same," or otherwise "the induction through any surface bounded by a closed curve depends only on the form and position of the closed curve, and not on that of the surface itself." The flux along the second circuit is called the "electric current," and is also a vector quantity, subject to the solenoid condition. Neither circuit is necessarily bound by the limits of the machine, and both may be and generally are sub-divided. Both these fluxes are produced by corresponding forces, called respectively "magnetic force" and electromotive force," which likewise are vector quantities, but are defined by reference to a line instead of by an area, as is the case with the fluxes. (Maxwell, "Treatise on Electricity and Magnetism," Vol. I., page 10.) The solenoidal condition for magnetic induction is a direct deduction for Coulomb's original experiments, verified by all subsequent observations in magnetism. We now require to know the relation between each force and its corresponding flux. Let us first inquire into the relation between the magnetic induction (B) and the magnetic force (H). Such a relation may be expressed by the general equation

$$B = f^{-1}(H).$$

The form of the function depends upon the medium in which the tube is drawn, and also upon the physical conditions of the medium. For air and all other gases, and generally for all substances classed as "non-magnetic," it is a linear function possessing one coefficient or constant only. For such substances the equation may be written

$$B = \mu H.$$

Since the numerical definition of H is at our disposal, we may so define H that μ is unity for all the substances above referred to, and write $B = H$.

For iron, and generally for all magnetic substances, H is not a linear function of B, and its expression will involve several constants depending upon the medium, and such physical conditions as temperature and strain, and its previous history. The determination of the form of the function for iron in particular has been the subject of a great number of experiments, but no general expression has yet been discovered, and it has usually been found most convenient to record the experimental results in the form of a curve referred to rectangular axes, in which the ordinates represent magnetic induction and the abscissæ magnetic force. Such curves have been fully investigated for iron of various composition, and under varying physical conditions, among others particularly by G. Wiedemann ("Die Lehre vom Galvanismus," Vol. II., p. 340, and *sequor*), Rowland (*Phil. Mag.*, Aug., 1873), Carl Barus and Vincent Strouhal (*Bulletin* of the United States Geological Survey, No. 14, 1885), J. Hopkinson (*Phil. Trans.* of R.S., Part II., 1885), J. A. Ewing (*Phil. Trans.* R.S., Part II., 1885, and Part II., 1886, and *Proc.* of R.S., Vol. XLII., p. 200, 1887). By reference to these memoirs it is now possible to construct the curve with fair accuracy for iron of any known composition. For convenience we may express the curve by the equation

$$B = \mu H;$$

μ is then the tangent of the angle which the tangent to the curve makes with the axis of x. It has received various names: by Sir William Thomson, "permeability" (Reprint of "Papers on Electricity and Magnetism," Vol. II., page 54); by Maxwell, "coefficient of magnetic induction" ("Treatise on Electricity and Magnetism," Vol. II., page 54); and again, "magnetic inductive capacity" (Vol. II., page 243).

Secondly, we require to know the relation between the E.M.F. and current. This is well known to be expressed by a linear relation, known as Ohm's law, involving one constant coefficient only, universally designated the "resistance."

$$E = R C,$$

E being the E.M.F. and C the current. As far as all experimental evidence goes, R and the reciprocal of μ possess the same two characteristics, viz., that for any given substances in any defined physical condition they are proportional to the length of tube considered, and inversely proportional to its cross section; μ may therefore without impropriety be called the reciprocal of the "magnetic resistance," but as expressing this analogy only. It must be distinctly remembered that for magnetic substances there is no such relation as Ohm's law.

Having now defined the relation between the fluxes and their corresponding forces, it remains to consider the relation between the fluxes themselves, dependent upon the relative motion of their circuits. This may be expressed in various ways, all of which are the expressions of Faraday's well known law; (*i.*) The line integral of the E.M.F round the electric circuit is the rate of decrease of the surface integral of magnetic induction through any area bounded by the circuit; or (*ii.*) the time integral of the total E.M.F. round the electric circuit together with the surface integral of the induction through the circuit is a constant quantity. Again, since the surface integral of any vector over any surface which satisfies the solenoidal condition can be expressed by a line integral round any closed curve bounding the surface, a new vector may be introduced called the "vector potential" of magnetic induction, which is such that its line integral round any circuit is equal to the surface integral of induction over any surface bounded by the circuit. Also the time integral of the E.M.F. in any circuit is the electro-magnetic momentum. Hence Faraday's law may be expressed (*iii.*) the electro-magnetic momentum of a circuit is the line integral of the vector potential round the circuit (Maxwell, Vol. II., pages 28 and 234).

Excluding for the moment the consideration of magneto machines with permanent magnets, and of machines in which iron plays no part whatever, we may more particularly consider that class of dynamos in which the magnetic field is produced by the use of iron excited by a current, and we then require to know the relation between the current and the induction in the magnetic field produced by the current. Faraday showed that the magnetic field in the neighbourhood of an electric current is the same as that of a magnetic shell bounded by the circuit of the current, and has therefore a similar mag-

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

negtic potential. This is expressed by saying (*iv.*) that the line integral of magnetic force round any closed curve is zero, provided the closed curve does not surround the electric current, and if the current passes through the closed curve, then the line integral is proportional to the number of times it passes through, and is equal to $4\pi n c$, where c is the current and n the number of times it passes through the closed curve.

If we take the magnetic units as fundamental, the propositions (*i.*) and (*iv.*) define the units of E.M.F. and current. On the other hand, if we start with the arbitrary units of E.M.F. and current, based on quite other considerations, the propositions define the units of magnetic induction and magnetic force in terms of these.

We have now the materials for a complete investigation of a dynamo of any given configuration and constructed of iron, whose magnetic qualities are known. It is required to determine the E.M.F. and current in the electric circuit, as its configuration relative to the magnetic circuit is changed by the application of external forces, and as the magnetic forces in the magnetic circuit are changed either by external electro-magnetic forces or electro-magnetic forces derived from the current circulating in the electric circuit. The magnetic circuit consists in general of four parts: (*i.*) The magnet limb, which is surrounded by coils of wire, through which the exciting current is passed, which may be derived either from external sources or may be part of the electric circuit of the machine. (*ii.*) The field pieces, or the extended polar extensions of the magnet limb, embracing the armature. (*iii.*) The air space being the necessary interval between the iron of the pole-pieces and the iron of the armature, or in cases where the armature contains no iron, the interval between the opposed pole pieces. This interval may be an entirely free air space or partially occupied with other non-magnetic matter, according to the particular type of machine. (*iv.*) The armature, or that part of the machine carrying that portion of the electric circuit which is subject to displacement under external forces. There may be other subsidiary portions of the machine—*e.g.*, the magnet limb may be divided into one or more portions connected by yokes, but as these may be treated in exactly the same way as the pole-pieces they do not require special consideration. Again, the magnet limb may be divided so as to form several magnetic circuits, each of which may be considered independently. In alternate current such sub-division is universal, and is not infrequent in continuous current machines.

The magnetic circuit is thus subject to magnetic forces due to the current in the armature and the current round the magnet limb. We must therefore, in the general case, take these as the two independent variables, which we may denote by C and c. Now, it may be assumed with sufficient accuracy that in the magnet limb the boundaries of the tube of magnetic induction are coincident with the boundaries of the iron, and the cross section of the tube the same as the cross section of the iron. Outside the limb a portion of the lines of force will complete a magnetic circuit through external space, and will not enter the pole-pieces. The extent of this leakage or induction, from which no useful effect is obtained, depends upon the configuration of the machine and the degree of saturation of the iron, and could be calculated therefrom; but as it can be experimentally determined for any machine with great ease, it is unnecessary to consider it further, and we may regard the total induction in the magnet limb as greater than the induction in the pole pieces in a constant ratio, which we will denote by ν_1. It is usual to construct the pole-pieces of large section compared with the magnet limb, and hence the section of the pole-pieces may again be taken as the section of the tube of induction; but as the lines of force leave the pole-pieces to cross the air space, we cannot ascribe any boundary to the tube, but in every machine a portion only can pass through the armature, and part must pass from one pole-piece to the other by lines external to the armature. Moreover, the relation between the two parts will not be a constant one, unless the magnetic forces in the armature are constant, which can never be the case. It is, therefore, necessary to consider the tube of induction, which crosses the air space and enters the armature, as a variable portion of the whole tube, the variation depending upon the magnetic forces in the armature. We may denote the ratio of the induction through the pole-pieces to the induction through the armature by ν_2. Knowing now the components of the magnet circuit, we can determine the magnetic forces in the several parts, and hence obtain the induction in the tube. Let A_1 be the cross section of the magnet limb, l_1 its length; A_2 the cross section of the pole pieces, l_2 the mean length of the tube therein; A_3 the cross section of the air space, comprising all the space through which the lines entering the armature pass, l_3 its length; A_4 the cross section of the iron of the armature (if it contains iron), and l_4 the mean length of the tube of force therein. Then the line integral of magnetic force taken round the circuit is

$$\frac{1}{\mu_1} l_1 \frac{\nu_1\nu_2 I}{A_1} + \frac{1}{\mu_2} l_2 \frac{\nu_2 I}{A_2} + \left(\frac{1}{\mu_3}\frac{l_3}{A_3} + \frac{1}{\mu_4}\frac{l_4}{A_4}\right) I,$$

the μ's being the coefficients of magnetic induction for the several portions of the circuit. For air the coefficient is unity, hence $\mu_3 = 1$. I is the total induction in the armature, which is assumed to be uniformly distributed over the tube. The integration has extended along the tube only which passes through the armature, and hence the forces along the portions of the whole tube which pass outside the machine do not appear. Now the magnetic circuit is cut by the current in the magnet coils and the current in the armature. Let n_1 be the number of times it is cut by the former, n_2 by the latter. Then

$$\frac{1}{\mu_1} l_1 \frac{\nu_1\nu_2 I}{A_1} + \frac{1}{\mu_2} l_2 \frac{\nu_2 I}{A_2} + \left(\frac{l_3}{A_3} + \frac{1}{\mu_4}\frac{l_4}{A_4}\right) I = 4\pi (n_1 c + n_2 C).$$

It must be noted that the direction in which the circuit is cut by c and C is in both cases taken to be positive. Referring to three rectangular axes and measuring the induction along the axis of z, the current round the magnets, along the axis of x, and that in the armature along the axis of y, the above equation may be written

$$l_1 f_1\left(\frac{\nu_1\nu_2 z}{A_1}\right) + l_2 f_2\left(\frac{\nu_2 z}{A_2}\right) + l_3 \frac{z}{A_3} + l_4 f_4\left(\frac{z}{A_4}\right) = 4\pi (n_1 x + n_2 y).$$

This represents a surface the ordinate at any point of which is the induction through the armature. Such a surface was first described by Dr. John Hopkinson (Lecture before the Inst. of C.E., April, 1883), and is called the "characteristic surface." It must be remembered ν_1 is a constant coefficient, or may be taken as such with sufficient accuracy, but ν_2 is not constant. It is unnecessary to consider further its general form, as it may better be determined in connection with the particular type of machine under consideration. f_1 f_2 f_4 would be the same functions if the quality of the iron were the same in the several portions of the machine.

Having obtained a general expression for the induction in the armature, the electromotive force in the electric circuit, when displaced, can be deduced by Faraday's law.

Consider now the application to alternate current machines. Such machines are usually multipolar. In machines of the disc type the number of poles is even, and the armature is divided into sections corresponding to the number of poles, and revolves uniformly between them. The tube through any one pair of opposed poles and back through another need only be considered, and the total effect of the machine obtained therefrom by summation. Suppose the iron of both magnets and armature so arranged that no currents are induced therein. There is then only one electric circuit to deal with. The whole current in one section of the armature cuts the magnetic tube passing through the section as many times as there are convolutions. Let m be the number of convolutions. The current x round the magnets is usually derived from independent sources, and maintained constant. For each such constant value the characteristic surface becomes a curve giving the relation between the induction through the armature and the current in it. The areas A_1, A_2, and A_4, and the lengths l_1, l_2, l_3, and l_4 are constant, but the area A_3 is a periodic function of the time, and can be expressed by a series of cosines, the coefficients of the series being determined by Fourier's theorem from the dimensions of the machine. The general consideration of the form of ν_2 has been worked out by Dr. J. Hopkinson (*Proc.* R.S., 1887), and need not be referred to further. The induction is a function of the time, but as an example consider

Digitized by Google

its value at that epoch when the cores of the armature are exactly opposed to the pole pieces.

$$\frac{l_1\nu_1\nu_2 I}{\mu_1 A_1}+\frac{l_2\nu_2 I}{\mu_2 A_2}+\left(\frac{l_3}{A_3}+\frac{l_4}{\mu_4 A_4}\right)I=4\pi n_1 c-4\pi m C.$$

Since the coefficients are all determinate by measurement or experiment, I is obtained in terms of c and C. Assume that, instead of continuous rotation of the armature, the action of the machine is such that each core of the armature is moved periodically in an infinitely short time from between one pair of poles to the next. Let T be the periodic time, E the electromotive force, then

$$E=m\frac{2\pi}{T}I.$$

Hence E is determined in terms of c and C. E is here the maximum E.M.F. The E.M.F. as measured by a Cardew voltmeter or equivalent instrument will be $\frac{1}{\sqrt{2}}$ of the maximum.

If the equation of the characteristic be differentiated with regard to the time, we shall obtain an equation of the form

$$A\dot{y}+By=\text{periodic function of } t,$$

when B is constant and A is a periodic function of t, but usually assumed to be constant, and called the "self induction" of the machine. In the case of an alternate current machine there are usually other magnetic forces acting upon the electric circuit external to the generating machine. For instance, the electric circuit may contain a transformer, or a second machine inserted as a motor, or an arc lamp in which there is a constant E.M.F. changing sign with the current. It is not, then, sufficient to consider the magnetic tube within the machine only, but the effect of all other tubes which are cut by the circuit must be included, and the characteristic surface of the whole system obtained by summation. These cases have been worked out, taking A as by Dr. J. Hopkinson (*Journal* of Tel. Engineers, 1884).

Now consider the application to continuous current machines. With the exception of certain types of dynamos, like that of Professor Forbes or the cylinder dynamo of Dr. Werner Siemens, in general no current continuous in direction can be obtained by continuous rotation of any part of the electric circuit, unless arrangement is made for reversing the current at a certain stage of each revolution. If the rotating part contained one section only, the current, though continuous in direction, would oscillate from zero to its maximum. To avoid this the electric circuit is divided into a number of sections, arranged symmetrically on the armature, the current in one or two of which only is reversed at a time. If the number of sections be even and equal to $2m$, one half will be in series, and one half the total current will pass through each half, except at the instant of commutation. At such time two sections are short circuited, and form complete circuits in which the current will be determined by the induction through them at the time; and the number of sections in series will be $\overline{m-1}$. If the number of sections be odd and equal to $\overline{2m+1}$, one section only will be commuted at a time, and at that instant there will be m sections in series. At other times there will be $\overline{m+1}$ sections in series on one side and m on the other, and consequently there will be a superposed current flowing through the armature only, due to the inequality in the number of sections in series in the two halves. In one revolution of the armature the tube of induction through it will be cut four times by each section, and if the plane of commutation is symmetrical with regard to the tube of induction the current in one half the sections will cut it in the opposite direction to that in the other half. In this case, $n_2=0$. But any displacement of the plane of commutation from the symmetrical position will cause the current in a greater number of sections to cut the tube in one direction than in the other. Let λ be the angular advance of the plane of commutation, and m the number of sections in the armature; then $n_2=\frac{\lambda m}{\pi}$. The value of λ may be fixed for any given machine, or varied at pleasure, or may be determined to avoid sparking at the time of commutation of a section. The general discussion of the value of λ to effect this has not yet been attempted. For the present λ must be regarded as independent. The general equation of the characteristic surface becomes for a continuous current machine,

$$l_1 f_1\left(\frac{\nu_1\nu_2 z}{A_1}\right)+l_2 f_2\left(\frac{\nu_2 z}{A_2}\right)+l_3\frac{z}{A_3}+l_4 f_4\left(\frac{z}{A_4}\right)=4\pi n_1 x-4\lambda m y,$$

λ being reckoned positive when the displacement is in the direction of rotation.

If no current passes through the armature $y=0$ and ν_2 may be taken as constant and determined by experiment. The equation may then be written

$$l_1 f_1\left(\frac{\nu_1\nu_2 z}{A_1}\right)+l_2 f_2\left(\frac{\nu_2 z}{A_2}\right)+l_3\frac{z}{A_3}+l_4 f_4\left(\frac{z}{A_4}\right)=4\pi n_1 x$$

which is the equation to the characterictic curve of a shunt-wound or separately-excited machine, and determines the induction for all values of the exciting current. Having determined the characteristic when $y=0$, the characteristic surface can be determined therefrom by considering the form of ν_2. (*See* J. and E. Hopkinson, *Trans.* of R.S., Part I., 1886, p. 334.)

It has been assumed that the sections of the armature are the only conductors in the field, or that the armature is so constructed that no currents circulate in the iron. This in the best machines is only partially attained. The effect of such currents on the characteristic surface is the same as increasing the current in the armature. If the lead is negative the induction is increased both by the current in the sections of the armature and in the iron; but such a negative lead must give rise to destructive sparking, as the sections will be commuted in a strong field.

ON THE MAGNETISATION OF IRON IN STRONG FIELDS.*

BY PROF. J. A. EWING, B.SC., F.R.S., AND WILLIAM LOW.

In March of the present year we communicated to the Royal Society (*Proceedings*, Vol. XLII., p. 200) the results of experiments on this subject, in which the magnetism of a narrow neck or isthmus of iron placed between the pole-pieces of a large electro-magnet was examined, by suddenly drawing out the piece, or turning it end for end so that the direction of its magnetisation was reversed. The piece examined was in the form of a bobbin with a short central neck, turned to a small diameter and with large spreading conical ends, which were in contact with the pole-pieces and provided an easy path for the lines of induction to converge to the central neck. The metal of the neck was in this way subjected to a much greater magnetic force than it would be practicable to produce by the direct action of a magnetising solenoid. The induction in the iron was measured ballistically by means of a coil of fine wire, in a single layer, round the iron neck. The magnetic force in the air space closely contiguous to the neck was also measured by means of a second or outer induction coil of a slightly greater diameter than the inner one. This determination of the field allowed a correction to be applied for the air space enclosed by the inner coil, and it also gave what was probably a close approximation to the value of the magnetic force within the metal itself.

The object of the present note is to describe shortly the results of further experiments of the same kind, the details of which may be reserved for subsequent publication.

In the former experiments an electro-magnet with pole-pieces 5½cm. square was used. The conical ends of the bobbins tested brought the central neck down to a diameter of 0·65cm. in one form of sample and 0·923cm. in another form. With this we succeeded in forcing the induction 𝔅 in Low-moor and Swedish wrought iron up to values lying between

* Abstract of paper read before the British Association Meeting at Manchester, Sept., 1887.

Digitized by Google

32,000 and 33,000 C.-G.-S. units, the strength of the magnetic field in the air close to the neck being then about 11,000 C.-G.-S. units.

Large as those values were, they have been greatly exceeded in the present series of experiments. In the former paper we pointed out that the magnetic induction of the iron examined showed no sign of approaching a maximum, and that the value to which it might be forced by the "isthmus" method depended on the scale of the experiments. Through the kindness of Prof. Tait in allowing the large electro-magnet of the Edinburgh University Laboratory to be brought to Dundee, we have now been able to subject iron to much higher magnetising forces, and to secure a much greater concentration of the lines of induction. The Edinburgh magnet is one of exceptional power. Its limbs, which are vertical, are about 60 cms. long, and the cores are 10·7 cms. in diameter. Rectangular blocks of soft wrought iron 9·6cms. square serve for pole-pieces. To allow the old bobbins to be effectively used we added a pair of conical intermediate pieces of soft iron, which virtually formed an extension of the conical ends of the bobbin. Between these the bobbin was placed, the form generally used being that described in the previous paper as sample A. The neck of this sample had originally a diameter of 0·923cm., and consequently a section of 0·669 square cm., or about $\frac{1}{140}$ that of the pole-pieces. As in the former experiments, the highest values of magnetism have been reached with Lowmoor iron, and nearly as high values with Swedish iron.

The same Lowmoor bobbin that had been formerly used (sample A) had its magnetism measured by withdrawing it from the field, while the magnet with all its numerous coils in series was excited by a current which ranged up to 40 amperes. At the highest value the induction $\mathfrak{B}$ in the neck was 38,000 C.-G.-S., and the outside field, close to the neck, was 18,900 C.-G.-S. A Swedish sample of the same shape gave an induction of 37,620 with a field of about the same force.

To push the induction to still higher values the Lowmoor sample was then turned down in the central neck until the diameter was reduced to 0·397cm. This made its section only $\frac{1}{740}$ of the section of the pole-pieces. Careful determinations, several times repeated, then gave for the highest induction the enormous value 43,500 C.-G.-S., the outside field being 25,620 C.-G.-S. Here, as in the other figures already given, the induction stated is that which is found after the air space enclosed by the inner coil is allowed for, and after a suitable allowance is made for the residual magnetism of the piece. The residual induction is only about 500 C.-G.-S. units.

The ratio $\frac{\mathfrak{B}}{\text{outside field}}$ in this extreme case is 1·7, and the quantity $\frac{\mathfrak{B} - \text{outside field}}{4\pi}$, which would be the intensity of magnetism $\mathfrak{T}$ if the magnetic force within the metal were identical in value with the outside field, is 1,420. In the former experiments this quantity had values which decreased from 1,680 to 1,620, while the induction increased from about 25,000 to 32,000. Here, with an induction of 43,500, it has fallen off to a much more marked extent. We cannot yet speak with any certainty as to the degree of approximation of this quantity to the intensity of magnetism $\mathfrak{T}$; unless, however, the mean magnetic force within the neck is much less than the force at the surface, the results show that $\mathfrak{T}$ is becoming less as the induction is being forced to these extreme values—in other words, that the iron is tending towards diamagnetism in the manner Weber's theory leads us to expect. The question is one of the greatest interest, and we are now endeavouring to obtain a better knowledge of the magnetic force within the metal by examining the variation of the force at short distances from the surface of the neck.

A final effort was made to force the induction in Lowmoor iron to higher values, by turning the central neck down still further, until its section was less than $\frac{1}{1500}$ of the section of the pole-pieces, and annealing the bobbin carefully before magnetising it. The value of $\mathfrak{B}$ then reached was 45,350 C.-G.-S. units, which is the greatest induction recorded in any of our experiments.

With cast-iron the induction has been forced to 31,270 C.-G.-S., by applying a magnetic force of 16,900.

DISCUSSION.

Lord RAYLEIGH said he had had no experience himself on this interesting subject of the induction of very high forces. The interest of it was apparent to all, but until they knew pretty definitely what did happen at the end of the curve, it was obvious that speculations as to the nature of magnetism were very premature. He hoped that Prof. Rowland would give the section the benefit of his views on the subject.

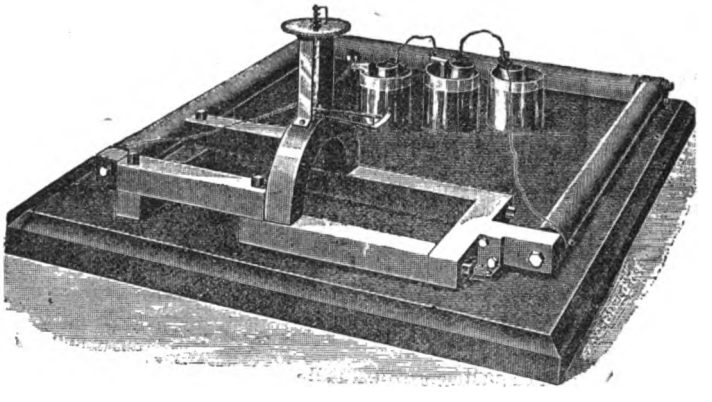
Prof. ROWLAND (of Baltimore) said that when he first made experiments on the lines suggested by the paper, he was, like Prof. Ewing, troubled with a little curvature at the end, and as he had experimented with rings of iron he attributed the circumstance to the iron not being homogeneous, and he turned off the off-side ring, which had been forged originally, and then more of it, with the result that he found that to some extent the curvature disappeared. Therefore, he ascribed the curvature to that cause. But his experiments were not sufficient to establish whether there was a maximum for the magnetic induction, or for the intensity of the magnetisation. He should say from those experiments that it was a decided maximum for the intensity of magnetisation. When one subtracted the intensity of the field from the magnetic induction, the results were very similar, and, as Prof. Ewing remarked, they then decreased in value, due possibly to an error in the experiments. He thought that they showed a decided maximum of magnetism, at a higher value than he gave, but the maximum was for the intensity of the magnetisation, and never for the magnetic induction. In that case he did not see any reason why the curvature should not be due to the original cause which he gave, which was want of homogeneity of iron. There were some particles in the original iron which did not attain their full power, but required a very strong field to magnetise them, and one could see very readily if one had a mixture of steel and soft iron that it would give a curve of this nature. He was not at all convinced himself but that the curving was something very similar to that he had recently given.

Prof. EWING observed that he ought to have said, with regard to the question whether that quantity had really passed the maximum, that it would require the field to be inaccurate to the extent of at least 12 per cent. to make the quantity really constant instead of apparently a descending one, as now appeared—that was to say, the field in the last set of experiments would have required to have been 22,000 instead of 25,000, in order to make the quantity constant. He did not know why want of homogeneity could be a possible cause of the curve taking the direction they now knew it to take. It seemed difficult to understand why the want of homogeneity in the iron should make it possible to get an induction of 45,000 C.-G.-S. units into it if a piece of pure iron stopped at 25,000 or so.

ON A MAGNETIC BRIDGE OR BALANCE FOR MEASURING MAGNETIC CONDUCTIVITY.*

BY THOMAS A. EDISON.

Perhaps no electric measuring instrument has proved more useful in practice, especially if we consider the various forms which it has assumed, than the device contrived by Christie and commonly known as Wheatstone's bridge. It was with a belief that a similar instrument could be constructed which should perform the same service for magnetic measurements that the experiments were made the results of which I have the honour now to present to the section.



The Wheatstone bridge is based upon the fact that if two points of different electric potentials are united by two conducting paths the fall of potential along these paths is absolutely the same provided that these paths are absolutely alike electrically. Consequently if two points equidistant from the place of higher potential be connected together no current will flow through the connecting wire. So by analogy, if two points be maintained at a constant difference of magnetic potential the fall of potential from one to the other through two or more paths will be absolutely uniform in all, provided these paths be magnetically identical. Hence, at any two points equi-distant from a given terminal, the magnetic potential is the same, and these points could be without differential action upon a magnetic pole.

The magnetic bridge may be constructed in the form of a rhomb, the

* Read before the American Association for the Advancement of Science, New York, August, 1887.

Digitized by Google

typical form of the Wheatstone bridge. For this purpose the four sides are made of the purest Norway iron, as soft as possible, and thoroughly annealed. To the acute angles of the rhomb are connected the poles of a long U-shaped electro-magnet, whose function is to develop the desired magnetic potential difference at these points. Connected to the two obtuse angles, and projecting inward, are two bars of Norway iron, similar in section to those forming the sides. Their inner ends, which are hollowed out, approach to within about half an inch of each other. Between these ends a stirrup is suspended by means of a silk fibre, which stirrup carries a short needle consisting of a thin tube of hardened steel well magnetised. To the stirrup is attached either a pointer moving over a graduated arc, or better, a mirror by means of which the deflection can be read in the usual way with a lampstand and scale.

In the instrument now in use in my laboratory (see accompanying illustrations) the magnetic bridge is in the form of a rectangle, the ends or poles of the electro-magnet being connected to the middle of the short sides, while the bars which pass inward to the needle are joined to the middle of the longer sides. The four halves of these longer sides constitute the sides of the bridge. The two at one end of the rectangle are fixed, the two at the other end are movable. The two bars which pass inward to the needle are curved so as to form a semicircle standing above the plane of the rectangle. The needle itself is similar in construction to that above described, but is suspended by a wire attached to a torsion head.

It will be readily seen that when the electro-magnet is charged, a constant difference of magnetic potential is maintained at the two ends of the rectangle, so that if the four bars constituting the sides of the bridge are magnetically identical, there will be no difference of magnetic potential between the ends of the bars which pass to the needle, and hence there will be no deflection. But if one of the moveable bars be loosened, the needle is at once deflected, and in a direction depending upon the side the bar occupies. If the bar is entirely removed the deflection is a maximum, of course. And if it be replaced by another bar differing in cross section, in quality of iron, or in any other way which affects the magnetic conductivity through the bridge, the deflection shows at once the amount of difference between that bar and the original one taken as a standard. The instrument is extraordinarily delicate, and the principal difficulties encountered in using it have arisen in the attempt to preserve this delicacy while at the same time the range of the apparatus is maintained.

The magnetic bridge was devised for the purpose of testing readily the quality of the iron purchased for the construction of dynamos. Very great variations are observed in irons supposed, commercially, to be of the same quality. Consequently the potential difference developed by a dynamo having field cores of such iron can never be exactly calculated. But by comparing the iron which is to be thus used in the magnetic bridge, its exact value for dynamo purposes may be determined, and the constants of the generator thus accurately calculated in advance.

But this bridge, it would seem, will be equally useful for testing iron and steel for other purposes. By its means not only may the character and quality of the metal be ascertained in terms of any desired standard, but flaws in the interior of a bar such as a car axle may be discovered at once.

Constructed with sufficient care and attention to details, the magnetic bridge may without doubt be made a most valuable instrument of precision for the furtherance of scientific research. The theory of its action is extremely simple, and it is the exact counterpart of an ordinary Wheatstone bridge constructed for measuring low resistance and immersed in salt water, since now whatever is true electrically of the one is true magnetically of the other. Not only may the laws of magnetic conductivity be investigated by means of this balance for all paramagnetic and diamagnetic bodies, but the variation of this conductivity under the action of various physical agencies, such as heat, pressure, strain, &c., may be determined.

EDISON'S PYRO-MAGNETIC DYNAMO.

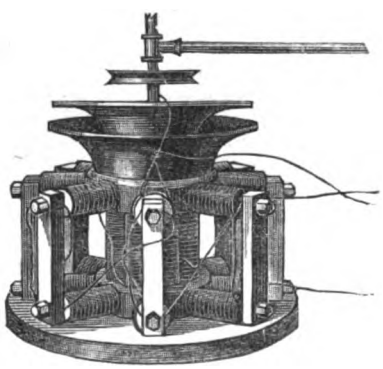


Fig. 1.

In our issue of last week we gave a full description of Edison's Pyro-Magnetic Dynamo, and we have since obtained drawings, from which the adjoining illustrations have been engraved. Figure 1 shows the upper part of the generator, which is placed as it stands upon the top of a furnace or stove. The hot air ascends through the upright iron tubes seen in the centre, and which are covered with asbestos and wound outside with the armature wires. The rectangular upright bars and horizontal coils represent the field-magnets. The rotating part is better seen in Figure 2, in which the field-magnets are removed. The rotating screen, which cuts off

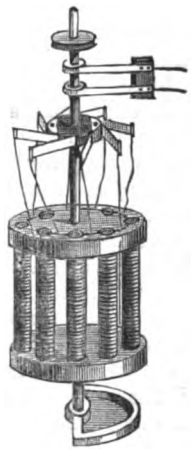

Fig. 2.

the hot air, is seen below, and above is the commutator and collecting brushes.

THE MIX AND GENEST MICROPHONE.

After repeated trials made by the German Postal Department with the microphones constructed by Messrs. Mix and Genest, these apparatus have been introduced in the place of the telephones and Bell-Blake microphones hitherto used in the telephone service. At present there are about 5,000 in use. This fact alone is a sufficient reason for giving our readers a description of this instrument.

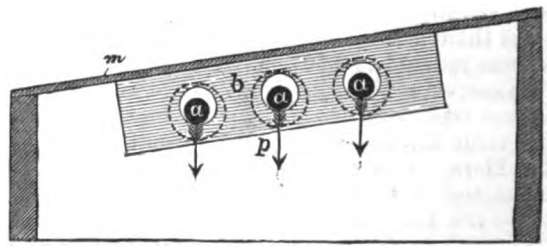

Fig. 1.

In microphones constructed after the system represented in Fig. 1 a kind of rattling noise is frequently occasioned, which borne along with the sound of the human voice causes an audible disturbance in the telephone. The chief causes of these disturbances may be ascribed to the fact that the carbon rollers in their journals *a* rest loose in the flutings of the beam *b*, which is fastened to the sound-plate *m*. Owing to the shocks given to the entire apparatus and independent of the oscillations of the sound-plate, they are set in motion and roll to and fro in their bearings.

In microphones in which the sound plates are arranged vertically, as shown in Fig. 2, these disturbances assume such a character that there is no possibility of understanding the speaker, for in this case the horizontally directed oscillations of the sound-plate *m* cause themselves a backward and forward motion on the part of the carbon rollers without increasing or decreasing at the same time the lying on pressure of the roller journals, and by doing so bring the places of contact one on the other, and thus occasion a conducting resistance of greater or less force. The circumstance serves as an explanation of the reason why the sound-plates in Ader's microphones are not arranged vertically, although this way of arranging them offers many advantages over a horizontal or slightly inclined arrangement of the sound-plates. Speaking is more convenient in the vertical arrangement, and moreover the plates can be fitted on to instruments better in this way.

These drawbacks are avoided in the apparatus by Messrs. Mix and Genest. A sort of braking contrivance operates on the carbon rollers in such a way as to prevent their journals from lying on the lower points in the flutings of the beams. Thus, for instance, if in a microphone with a horizontal sound plate, as illustrated in Fig. 3, the carbon rollers are pressed upwards by outward force, it is evident that only a very trifling rolling and disturbing motion can occur, and only small pieces of carbon can be knocked off, which would act injuriously as a secondary contact. The same may be said of the journals of microphones with vertical sound plates, as represented

Digitized by Google

in Fig. 4, when the carbon rollers are pressed in the direction of the arrow *p*—that is to say, against the sound-plate. In this case the journals *a* are fixed in the flutings of the beams *b* in a direction given them by the power and gravity operating on them, which is clearly represented in the accompanying design, Fig. 4.

In all such cases the regulating contrivance applied to brake the carbon rollers in their motion has the result that only the oscillations transmitted from the sound-plate on to the contacts come in operation, whereas disturbing mechanical shocks resulting from any outward influences occasion no, or at least very insignificant, vibrations, which are not perceptible in the telephone. The separate contacts thus form a firm system with the sound-plate, so that the

FIG. 2.

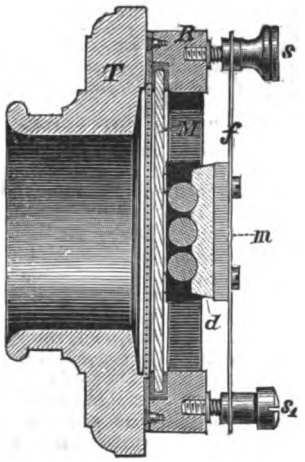

FIG. 6.

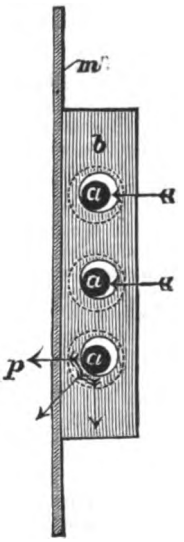

FIG. 4.

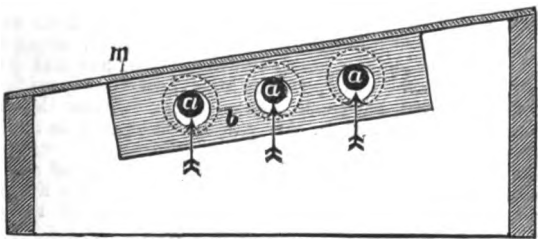

FIG. 3.

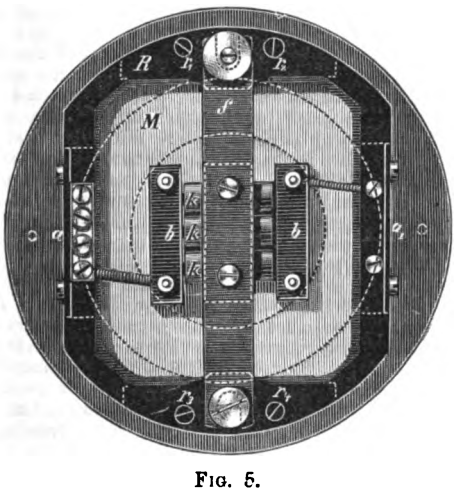

FIG. 5.

former are influenced in their motions and effects solely and alone by the shocks and oscillations which operate direct on these sound-plates. The rolling motion of the carbon rollers is thus removed in this way, and the distinctness of the words spoken is greatly augmented. This has been proved most effectually by the trials that have been instituted with this apparatus.

The above Figures 4 and 5 show the microphone in side view and cross section.

A metal ring, R (see Fig. 5), is fastened by means of the 4 screws r_1 r_2 r_3 r_4 on to a wooden mouth-piece; in a recess of the above ring is the diaphragm M, which is provided on its outer edge with an indiarubber band and is held in position by the two clamps *a* and a_1. The diaphragm is cut out of finely fibred firwood and is well lacquered to preserve it against dampness. On it there are two carbon beams *b*, and in the perforations of the latter are the journals of the carbon rollers *k*. The alterations in contact take place in the touching points. The cross piece *f* that runs straight across the carbon rollers serves as a braking contrivance, which is regulated as may be necessary by the large projecting screws.

Fig. 6 shows the apparatus in cross section. T is the mouthpiece, R the metal ring, M the diaphragm, *f* the braking cross-piece. On the latter is a metal block fastened by means of two screws. On this metal block is a soft elastic strip, *d*, of felt or similar material. The letters *s* and s_1 indicate the regulating screws for the braking contrivance.

One simple regulation of the microphone suffices for the installation, and there is no danger of its getting out of order, as is too often the case with Blake's microphone.

THE BRITISH ASSOCIATION MEETING AT MANCHESTER, 1887.

THE PRESIDENT'S ADDRESS.

(Concluded from page 365.)

In spite of these predictions, and in spite of Wöhler's memorable discovery in 1828 of the artificial production of ures, which did in reality break down for ever the barrier of essential chemical difference between the products of the inanimate and of the animate world, still, even up to a much later date, contrary opinions were held, and the synthesis of urea was looked upon as the exception which proves the rule. So it came to pass that for many years the artificial production of any of the more complicated organic substances was believed to be impossible. Now the belief in a special vital force has disappeared like the *ignis fatuus*, and no longer lures us in the wrong direction. We know now that the same laws regulate the formation of chemical compounds in both animate and inanimate nature, and the chemist only asks for a knowledge of the constitution of any definite chemical compound found in the organic world in order to be able to promise to prepare it artificially.

But the progress of synthetic organic chemistry, which has of late been so rapid, was made in the early days of the half-century only by feeble steps and slow. Seventeen long years elapsed between Wöhler's discovery and the real synthesis. This was accomplished by Kolbe, who in 1845 prepared acetic acid from its elements. But then a splendid harvest of results gathered in by chemists of all nations quickly followed, a harvest so rich and so varied that we are apt to be overpowered by its wealth, and amidst so much that is alluring and striking we may well find it difficult to choose the most appropriate examples for illustrating the power and the extent of modern chemical synthesis.

Next, as a contrast to our picture, let us for a moment glance back again to the state of things fifty years ago, and then notice the chief steps by which we have arrived at our present position. In 1837 organic chemistry possessed no scientific basis, and therefore no classification of a character worthy of the name. Writing to Berzelius in that year, Wöhler describes the condition of organic chemistry as one enough to drive a man mad. "It seems to me," says he, "like the tropical forest primæval, full of the strangest growths, an endless and pathless thicket in which a man may well dread to wander." Still clearances had already been made in this wilderness of facts. Berzelius in 1832 welcomed the results of Liebig and Wöhler's research on benzoic acid as the dawn of a new era; and such it really was, inasmuch as it introduced a novel and fruitful idea, namely, the possibility of a group of atoms acting like an element by pointing out the existence of organic radicles. This theory was strengthened and confirmed by Bunsen's classical researches on the cacodyl compounds, in which he showed that a common group of elements which acts exactly as a metal can exist in the free state, and this was followed soon afterwards by isolation of the so-called alcohol radicles by Frankland and Kolbe. It is, however, to Schorlemmer that we owe our knowledge of the true constitution of these bodies, a matter which proved to be of vital importance for the further development of science.

Turning our glance in another direction we find that Dumas, in 1834, by his law of substitution threw light upon a whole series of singular and unexplained phenomena by showing that an exchange can take place between the constituent atoms in a molecule. Laurent, indeed, went farther, and assumed that a chlorine atom, for example, took up the position vacated by an atom of hydrogen and played the part of its displaced rival, so that the chemical and physical properties of the substitution-product were thought to remain substantially the same as those of the original body. A singular story is connected with this discovery. At a *soirée* in the Tuileries in the time of Charles X. the guests were almost suffocated by acrid vapours which were evidently emitted by the burning wax candles, and the great chemist Dumas was called in to examine into the cause of the annoyance. He found that the wax of which the candles were made had been bleached by chlorine, that a replacement of some of the hydrogen atoms of the wax by chlorine had occurred, and that the suffocating vapours consisted of hydrochloric acid given off during the combustion. The wax was as white and odourless as before, and the fact of the substitution of chlorine for hydrogen could only be recognised when the candles were destroyed by burning. This incident induced Dumas to investigate more closely this class of phenomena, and the results of this investigation are embodied in his law of substitution. So far, indeed, did the interest of the French school of chemists lead them that

Digitized by Google

some assumed that not only the hydrogen but also the carbon of organic bodies could be replaced by substitution. Against this idea Liebig protested, and in a satirical vein he informs the chemical public, writing from Paris under the *nom de plume* of S. Windler, that he has succeed in substituting not only the hydrogen but the oxygen and carbon in cotton cloth by chlorine, and he adds that the London shops are now selling nightcaps and other articles of apparel made entirely of chlorine, goods which meet with much favour, especially for hospital use!

But the debt which chemistry, both inorganic and organic, thus owes to Dumas' law of substitution is serious enough, for it proved to be the germ of Williamson's classical researches on etherefication, as well as of those of Wurtz and Hofmann on the compound ammonias, investigations which lie at the base of the structure of modern chemistry. Its influence has been, however, still more far-reaching, inasmuch as upon it depends in great measure the astounding progress made in the wide field of organic synthesis.

It may here be permitted to me to sketch in rough outline the principles upon which all organic syntheses have been effected. We have already seen that as soon as the chemical structure of a body has been ascertained, its artificial preparation may be certainly anticipated, so that the first step to be taken is the study of the structure of the naturally occurring substance which it is desired to prepare artificially by resolving it into simpler constituents, the constitution of which is already known. In this way, for example, Hofmann discovered that the alkaloid coneine, the poisonous principle of hemlock, may be decomposed into a simpler substance well known to chemists under the name of pyridine. This fact having been established by Hofmann, and the grouping of the atoms approximately determined, it was then necessary to reverse the process, and, starting with pyridine, to build up a compound of the required constitution and properties, a result recently achieved by Ladenburg in a series of brilliant researches. The well-known synthesis of the colouring matter of madder by Graebe and Liebermann, preceded by the important researches of Schunck, and that of indigo by Baeyer, are other striking examples in which this method has been successfully followed.

Not only has this intimate acquaintance with the changes which occur within the molecules of organic compounds been utilised, as we have seen, in the synthesis of naturally occurring substances, but it has also led to the discovery of many new ones. Of these perhaps the most remarkable instance is the production of an artificial sweetening agent termed saccharin, 250 times sweeter than sugar, prepared by a complicated series of reactions from coal-tar. Nor must we imagine that these discoveries are of scientific interest only, for they have given rise to the industry of the coal-tar colours, the value of which is measured by millions sterling annually, an industry which Englishmen may be proud to remember was founded by our countryman Perkin.

Another interesting application of synthetic chemistry to the needs of everyday life is the discovery of a series of valuable febrifuges, amongst which I may mention antipyrin as the most useful. An important aspect in connection with the study of these bodies is the physiological value which has been found to attach to the introduction of certain organic radicles, so that an indication is given of the possibility of preparing a compound which will possess certain desired physiological properties, or even to foretell the kind of action which such bodies may exert on the animal economy.

But it is not only the physiological properties of chemical compounds which stand in intimate relation with their constitution, for we find that this is the case with all their physical properties. It is true that at the beginning of our period any such relation was almost unsuspected, whilst at the present time the number of instances in which this connection has been ascertained is almost infinite. Amongst these perhaps the most striking is the relationship which has been pointed out between the optical properties and chemical composition. This was in the first place recognised by Pasteur in his classical researches on racemic and tartaric acids in 1848; but the first to indicate a quantitative relationship and a connection between chemical structure and optical properties was Gladstone in 1863. Great instrumental precision has been brought to bear on this question, and consequently most important practical applications have resulted. I need only refer to the well-known accurate methods now in everyday use for the determination of sugar by the polariscope, equally valuable to the physician and to the manufacturer.

But now the question may well be put, Is any limit set to this synthetic power of the chemist? Although the danger of dogmatising as to the progress of science has already been shown in too many instances, yet one cannot help feeling that the barrier which exists between the organised and unorganised worlds is one which the chemist at present sees no chance of breaking down.

It is true that there are those who profess to foresee that the day will arrive when the chemist, by a succession of constructive efforts, may pass beyond albumen, and gather the elements of lifeless matter into a living structure. Whatever may be said regarding this from other standpoints, the chemist can only say that at present no such problem lies within his province. Protoplasm, with which the simplest manifestations of life are associated, is not a compound, but a structure built up of compounds. The chemist may successfully synthesise any of its component molecules, but he has no more reason to look forward to the synthetic production of the structure than to imagine that the synthesis of gallic acid leads to the artificial production of gall-nuts.

Although there is thus no prospect of our effecting a synthesis of organised material, yet the progress made in our knowledge of the chemistry of life during the last fifty years has been very great, and so much so, indeed, that the sciences of physiological and of pathological chemistry may be said to have entirely arisen within this period.

In the introductory portion of this address I have already referred to the relations supposed to exist fifty years ago between vital phenomena and those of the inorganic world. Let me now briefly trace a few of the more important steps which have marked the progress of this branch of science during this period. Certainly no portion of our science is of greater interest, nor, I may add, of greater complexity than that which, bearing on the vital functions both of plants and of animals, endeavours to unravel the tangled skein of the chemistry of life, and to explain the principles according to which our bodies live and move and have their being. If, therefore, in the less complicated problems with which other portions of our science has to deal, we find ourselves, as we have seen, often far from possessing satisfactory solutions, we cannot be surprised to learn that with regard to the chemistry of the living body—whether vegetable or animal—in health or disease we are still farther from a complete knowledge of phenomena, even those of fundamental importance.

It is of interest here to recall the fact that nearly fifty years ago Liebig presented to the Chemical Section of this Association a communication in which, for the first time, an attempt was made to explain the phenomena of life on chemical and physical lines, for in this paper he admits the applicability of the great principle of the conservation of energy to the functions of animals, pointing out that the animal cannot generate more heat than is produced by the combustion of the carbon and hydrogen of his food.

"The source of animal heat," says Liebig, "has previously been ascribed to nervous action, or to the contraction of the muscles, or even to the mechanical motions of the body, as if these motions could exist without an expenditure of force [equal to that] consumed in producing them." Again, he compares the living body to a laboratory furnace in which a complicated series of changes occur in the fuel, but in which the end-products are carbonic acid and water, the amount of heat evolved being dependent, not upon the intermediate, but upon the final products. Liebig asked himself the question, does every kind of food go to the production of heat; or can we distinguish, on the one hand, between the kind of food which goes to create warmth, and, on the other, that by the oxidation of which the motions and mechanical energy of the body are kept up? He thought that he was able to do this, and he divided food into two categories; the starchy or carbohydrate food is that, said he, which by its combustion provides the warmth necessary for the existence and life of the body. The albuminous or nitrogenous constituents of our food, the flesh meat, the gluten, the casein out of which our muscles are built up, are not available for the purposes of creating warmth, but it is by the waste of those muscles that the mechanical energy, the activity, the motions of the animal are supplied. We see, said Liebig, that the Esquimaux feeds on fat and tallow, and this burning in his body keeps out the cold. The Gaucho, riding on the pampas, lives entirely on dried meat, and the rowing man and pugilist, trained on beefsteaks and porter, require little food to keep up the temperature of their bodies, but much to enable them to meet the demand for fresh muscular tissue, and for this purpose they need to live on the strongly nitrogenous diet.

Thus far Liebig. Now let us turn to the present state of our knowledge. The question of the source of muscular power is one of the greatest interest, for, as Frankland observes, it is the corner-stone of the physiological edifice and the key to the nutrition of animals.

Let us examine by the light of modern science the truth of Liebig's view—even now not uncommonly held—as to the functions of the two kinds of food, and as to the cause of muscular exercise being the oxidation of the muscular tissue. Soon after the promulgation of these views, J. R. Mayer, whose name as the first expositor of the idea of the conservation of energy is so well known, warmly attacked them, throwing out the hypothesis that all muscular action is due to the combustion of food and not to the destruction of muscle, proving his case by showing that if the muscles of the heart be destroyed in doing mechanical work the heart would be burnt up in eight days! What does modern research say to this question? Can it be brought to the crucial test of experiment? It can; but how? Well, in the first place we can ascertain the work done by a man or any other animal: we can measure this work in terms of our mechanical standard, in kilogramme metres or foot-pounds. We can next determine what is the destruction of nitrogeneous tissue at rest and under exercise by the amount of nitrogenous material thrown off by the body. And here we must remember that these tissues are never completely burnt, so that free nitrogen is never eliminated. If, now, we know the heat value of the burnt muscle, it is easy to convert this into its mechanical equivalent, and thus measure the energy generated. What is the result? Is the weight of muscle destroyed by ascending the Faulhorn or by working on the treadmill sufficient to produce on combustion heat enough when transformed into mechanical exercise to lift the body up to the summit of the Faulhorn or to do the work on the treadmill? Careful experiment has shown that this is so far from being the case that the actual energy developed is twice as great as that which could possibly be produced by the oxidation of the nitrogenous constituents eliminated from the body during twenty-four hours. That is to say, taking the amount of nitrogenous substance cast off from the body, not only whilst the work was being done but during twenty-four hours, the mechanical effect capable of being produced by the muscular tissue from which this cast-off material is derived would only raise the body halfway up the Faulhorn, or enable the prisoner to work half his time on the treadmill.

Hence it is clear that Liebig's proposition is not true. The nitrogeneous constituents of the food do doubtless go to repair the waste of muscle, which, like every other portion of the body, needs renewal, whilst the function of the non-nitrogenous food is not only to supply the animal heat, but also to furnish, by its oxidation, the muscular energy of the body.

We thus come to the conclusion that it is the potential energy of the food which furnishes the actual energy of the body, expressed in terms either of heat or of mechanical work.

Digitized by Google

But there is one other factor which comes into play in this question of mechanical energy, and must be taken into account; and this factor we are as yet unable to estimate in our usual terms. It concerns the action of the mind upon the body, and, although incapable of exact expression, exerts none the less an important influence on the physics and chemistry of the body, so that a connection undoubtedly exists between intellectual activity or mental work and bodily nutrition. In proof that there is a marked difference between voluntary and involuntary work, we need only compare the mechanical action of the heart, which never causes fatigue, with that of the voluntary muscles, which become fatigued by continued exertion. So, too, we know well that an amount of drill which is fatiguing to the recruit is not felt by the old soldier, who goes through the evolutions automatically. What is the expenditure of mechanical energy which accompanies mental effort is a question which science is probably far removed from answering. But that the body experiences exhaustion as the result of mental activity is a well-recognised fact. Indeed, whilst the second law of thermodynamics teaches that in none of the mechanical contrivances for the conversion of heat into actual energy can such a conversion be complete, it is perhaps possible, as Helmholtz has suggested, that such a complete conversion may take place in the subtle mechanism of the animal organism.

The phenomena of vegetation, no less than those of the animal world, have, however, during the last fifty years been placed by the chemist on an entirely new basis. Although before the publication of Liebig's celebrated report on chemistry and its application to agriculture, presented to the British Association in 1840, much had been done, many fundamental facts had been established, still Liebig's report marks an era in the progress of this branch of our science. He not only gathered up in a masterly fashion the results of previous workers, but put forward his own original views with a boldness and frequently with a sagacity which gave a vast stimulus and interest to the questions at issue. As a proof of this I may remind you of the attack which he made on, and the complete victory which he gained over, the humus theory. Although Saussure and others had already done much to destroy the basis of this theory, yet the fact remained that vegetable physiologists up to 1840 continued to hold to the opinion that humus, or decayed vegetable matter, was the only source of the carbon of vegetation. Liebig, giving due consideration to the labours of Saussure, came to the conclusion that it was absolutely impossible that the carbon deposited as vegetable tissue over a given area, as for instance over an area of forest land, could be derived from humus, which is itself the result of the decay of vegetable matter. He asserted that the whole of the carbon of vegetation is obtained from the atmospheric carbonic acid, which, though only present in the small relative proportion of 4 parts in 10,000 of air, is contained in such absolutely large quantity that if all the vegetation on the earth's surface were burnt, the proportion of carbonic acid which would thus be thrown into the air would not be sufficient to double the present amount.

That this conclusion of Liebig's is correct needed experimental proof, but such proof could only be given by long-continued and laborious experiment, and this serves to show that chemical research is not now confined to laboratory experiments lasting perhaps a few minutes, but that it has invaded the domain of agriculture as well as of physiology, and reckons the periods of her observations in the field not by minutes but by years It is to our English agricultural chemists, Lawes and Gilbert, that we owe the complete experimental proof required. And it is true that this experiment was a long and tedious one, for it has taken forty-four years to give the definite reply. At Rothamsted a plot was set apart for the growth of wheat. For forty-four successive years that field has grown wheat without addition of any carbonised manure; so that the only possible source from which the plant could obtain the carbon for its growth is the atmospheric carbonic acid. Now, the quantity of carbon which on an average was removed in the form of wheat and straw from a plot manured only with mineral matter was 1,000 pounds, whilst on another plot, for which a nitrogenous manure was employed, 1,500 pounds more carbon was annually removed; or 2,500 pounds of carbon are removed by this crop annually without the addition of any carbonaceous manure. So that Liebig's prevision has received a complete experimental verification.

May I, without wearying you with experimental details, refer for a moment to Liebig's views as to the assimilation of nitrogen by plants—a much more complicated and difficult question than the one we have just considered—and compare these with the most modern results of agricultural chemistry? We find that in this case his views have not been substantiated. He imagined that the whole of the nitrogen required by the plant was derived from atmospheric ammonia; whereas Lawes and Gilbert have shown by experiments of a similar nature to those just described, and extending over a nearly equal length of time, that this source is wholly insufficient to account for the nitrogen removed in the crop, and have come to the conclusion that the nitrogen must have been obtained either from a store of nitrogenous material in the soil or by absorption of free nitrogen from the air. These two apparently contradictory alternatives may perhaps be reconciled by the recent observations of Warrington and of Berthelot, which have thrown light upon the changes which the so-called nitrogenous capital of the soil undergoes, as well as upon its chemical nature, for the latter has shown that under certain conditions the soil has the power of absorbing the nitrogen of the air, forming compounds which can subsequently be assimilated by the plant.

Touching us as human beings even still more closely than the foregoing, is the influence which chemistry has exerted on the science of pathology, and in no direction has greater progress been made than in the study of micro-organisms in relation to health and disease. In the complicated chemical changes to which we give the names of fermentation and putrefaction, the views of Liebig, according to which these phenomena are of a purely chemical character, have given way under the searching investigations of Pasteur, who established the fundamental principle that these processes are inseparably connected with the life of certain low forms of organisms. Thus was founded the science of bacteriology which in Lister's hands has yielded such splendid results in the treatment of surgical cases; and in those of Klebs, Koch, and others has been the means of detecting the cause of many diseases both in man and animals; the latest, and not the least important of which is the remarkable series of successful researches by Pasteur into the nature and mode of cure of that most dreadful of maladies—hydrophobia. And here I may be allowed to refer with satisfaction to the results of the labours on this subject of a committee, the formation of which I had the honour of moving for in the House of Commons. These results confirm in every respect Pasteur's assertions, and prove beyond a doubt that the adoption of his method has prevented the occurrence of hydrophobia in a large proportion of persons bitten by rabid animals, who, if they had not been subjected to this treatment, would have died of that disease. The value of his discovery is, however, greater than can be estimated by its present utility, for it shows that it may be possible to avert other diseases besides hydrophobia by the adoption of a somewhat similar method of investigation and of treatment. This, though the last, is certainly not the least of the debts which humanity owes to the great French experimentalist. Here it might seem as if we had outstepped the boundaries of chemistry, and have to do with phenomena purely vital. But recent research indicates that this is not the case, and points to the conclusion that the microscopist must again give way to the chemist, and that it is by chemical rather than by biological investigation that the causes of diseases will be discovered, and the power of removing them obtained. For we learn that the symptoms of infective diseases are no more due to the microbes which constitute the infection than alcoholic intoxication is produced by the yeast-cell, but that these symptoms are due to the presence of definite chemical compounds, the result of the life of these microscopic organisms. So it is to the action of these poisonous substances formed during the life of the organism, rather than to that of the organism itself, that the special characteristics of the disease are to be traced; for it has been shown that the disease can be communicated by such poisons in entire absence of living organisms.

If I have thus far dwelt on the progress made in certain branches of pure science it is not because I undervalue the other methods by which the advancement of science is accomplished, viz., that of the application and of the diffusion of a knowledge of nature, but rather because the British Association has always held, and wisely held, that original investigation lies at the root of all application, so that to foster its growth and encourage its development has for more than fifty years been our chief aim and wish.

Had time permitted I should have wished to have illustrated this dependence of industrial success upon original investigation, and to have pointed out the prodigious strides which chemical industry in this country has made during the fifty years of Her Majesty's reign. As it is, I must be content to remind you how much our modern life, both in its artistic and useful aspects, owes to chemistry, and, therefore, how essential a knowledge of the principles of the science is to all who have the industrial progress of the country at heart.

This leads me to refer to what has been accomplished in this country of ours towards the diffusion of scientific knowledge amongst the people during the Victorian era. It is true that the English people do not possess, as yet, that appreciation of the value of science so characteristic of some other nations. Up to very recent years our educational system, handed down to us from the middle ages, has systematically ignored science, and we are only just beginning, thanks in a great degree to the prevision of the late Prince Consort, to give it a place, and that but an unimportant one, in our primary and secondary schools or in our universities. The country is, however, now awakening to the necessity of placing its house in order in this respect, and is beginning to see that if she is to maintain her commercial and industrial supremacy the education of her people from top to bottom must be carried out on new lines. The question as to how this can be most safely and surely accomplished is one of transcendent national importance, and the statesman who solves this educational problem will earn the gratitude of generations yet to come.

In conclusion, may I be allowed to welcome the unprecedentedly large number of foreign men of science who have on this occasion honoured the British Association by their presence, and to express the hope that this meeting may be the commencement of an international scientific organisation, the only means nowadays existing, to use the words of one of the most distinguished of our guests, of establishing that fraternity among nations from which politics appear to remove us further and further by absorbing human powers and human work, and directing them to purposes of destruction. It would indeed be well if Great Britain, which has hitherto taken the lead in so many things that are great and good, should now direct her attention to the furthering of international organisations of a scientific nature. A more appropriate occasion than the present meeting could perhaps hardly be found for the inauguration of such a movement.

But whether this hope be realised or not, we all unite in that one great object, the search after truth for its own sake, and we all, therefore, may join in re-echoing the words of Lessing: "The worth of man lies not in the truth which he possesses, or believes that he possesses, but in the honest endeavour which he puts forth to secure that truth; for not by the possession of truth but by the search after it are the faculties of man enlarged, and in this alone consists his ever-growing perfection. Possession fosters content, indolence, and pride. If God should hold in His right hand all truth, and in His left hand the ever-active desire to seek truth, though with the condition of perpetual error, I would humbly ask for the contents of the left hand, saying, 'Father, give me this; pure truth is only for Thee.'"

COMPANIES' MEETINGS & REPORTS.

Manchester and District Edison Electric Light Company.

The annual meeting of this Company was held at the Memorial Hall, Albert-square, Manchester, on Monday last, under the presidency of Mr. V. K. Armitage, when the following report of the Directors was taken as read :—

"The balance sheet, though showing only a slight improvement on the previous year's work of the Company, confirms the opinion expressed by the Directors at the last annual meeting, that the prospect of work to be done in the future is more favourable. Applications for estimates of the cost of installing the electric light are more numerous, and the interest taken by the public is more practical than in former years, indicating that this system of lighting is coming more in favour the better it is understood. Since the last meeting of the Company the Directors have terminated the central installation in Mount-street, and, consequently, the heavy expenses in connection with that establishment, the lease of which expires in December, are practically at an end. The lease of the Company's show room and offices also expires this year, and in seeking fresh premises the Directors are actuated by a desire to reduce the present expenses of the show room, which, as an advertising medium, is not any longer necessary. The reduction in the expenses which the above changes will bring about will better enable the Company to meet the great competition they have to encounter, and this, coupled with an anticipated increase of business, will no doubt place it in the power of the Directors to make a much more satisfactory report next year. The value of the incandescent lamp patents held in the Manchester district by this Company has been considerably enhanced by the judgment given in favour of the Edison and Swan United Company having been sustained in the Court of Appeal. Two of the Directors, Sir Joseph C. Lee and J. C. Waterhouse, Esq , retire in accordance with the Company's Articles of Association ; they are, however, eligible, and offer themselves for re-election."

The CHAIRMAN, in moving the adoption of the report, expressed himself very hopeful with regard to the future of the Company, which had, he said, done work of an admirable quality during the past year. A striking proof of that was to be seen at the Jubilee Exhibition at Old Trafford, for there had not been a single word of complaint with regard to the work which the Company had done there. Another reason for congratulation was found in the fact that the value of the incandescent lamp patents held in the Manchester district by the Company had been considerably enhanced in consequence of the judgment given in favour of the Edison and Swan United Company having been sustained in the Court of Appeal.

The report having been adopted, the retiring Directors, Sir Joseph C. Lee and Mr. J. S. Waterhouse, were re-elected.

It was subsequently decided to alter the name of the Company to the "Manchester Edison-Swan Company (Limited)."

After a vote of thanks to the Chairman and Directors the meeting terminated.

NEW COMPANIES REGISTERED.

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—A company having this title has just been registered with a capital of £1,000,000, in £5 shares, for the purpose of acting as undertakers for the supply of electricity for lighting and other purposes within the City of London and the area included in the London postal district. The first directors are : The Hon. Reginald T. D. Brougham, the Right Hon. the Earl of Crawford, Francis Ince, Sir Coutts Lindsay, Bart., Joseph Pyke, Arthur Henry Wade, and the Right Hon. the Lord Wantage, V.C., K.C.B. The directors are to be entitled in each year to fees of £2,000 ; and, in addition, one-tenth of the surplus profits of the year, after providing the reserve fund and paying the shareholders a dividend of 5 per cent. But provision is made that the total remuneration shall not exceed £500 per annum in respect to each £1,000,000 of capital from time to time issued.

UNIVERSAL ELECTRIC COMPANY (LIMITED).—Registered by Elmslie, Forsyth and Elmslie, 27, Leadenhall-street, E.C., with a capital of £50,000 in £5 shares. Object, to carry on in any part of the world the business of an electric light company in all its branches, and in particular to lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps, and such other works as may be needful or convenient to generate, accumulate, distribute and supply electricity, and to light cities, towns, streets, docks, markets, theatres, buildings, and any other places, both public and private, and to form electric exchanges or centres. The first subscribers are :—

	Shares.
C. Capito, M.E., 63, Queen Victoria-street, E.C.	1
M. P. Hard, electrical engineer, 63, Queen Victoria-street	1
E. Damiquet, 24, Rue Baudin, Paris	1
A. de Cavaillon, engineer, 24, Rue Baudin, Paris	1
Thos. Fardon, M.E., Luton	1
J. R. Marsh, accountant, Luton	1
W. N. de Mattos, merchant, 27, Leadenhall-street	1

The remuneration of the directors shall be £200 per annum, which sum shall be divided among them in such proportions and manner as the directors shall determine. The managing directors are Charles Capito, Eugène Damiquet and Anthony de Cavaillon, and they shall be entitled to hold that office for a period of ten years certain, during good conduct, and they shall receive the remuneration of £100 per annum so long as they hold such office ; but when and so soon as 5,000 lamps are in operation by the company, such salary shall be increased to £300 per annum, and, in addition, they shall be entitled to one-half of the surplus net profits of the company after a dividend of not less than £15 per cent. per annum on the capital has been declared and paid to the shareholders, the right to such share of profits to be continued for a period of fifteen years.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 2nd inst. amounted to £3,543.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of August was 2,983, estimated to produce £2,250, against 2,848 messages, producing £2,163 in the corresponding month of last year. The traffic receipts for the month of May, estimated to produce £3,050, realised £3,061.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of August amounted to £1,614, against £1,379 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—This company's traffic receipts for the month of August amounted to £43,609, against £44,091 for the corresponding period of 1886, a decrease of £482.

EASTERN EXTENSION AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of August amounted to £36,274, and to £34,687 in the corresponding period of 1886, showing an increase of £1,587.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of August were £23,600 ; from 1st January to 31st August, they amounted to £174,120 ; while for the corresponding months of 1886 and 1835, they amounted to £169,960 and £192,040 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended September 2nd, amounted to £2,820, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending 31st August amounted to £4,525.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 31st August are £2,010, as compared with £2,003 in the corresponding period of 1886. The May receipts, estimated at £5,651, realised £5,737.

NOTES.

GENOA.—A very extensive project for lighting this town by electricity is now on foot. It is probable that the Zipernowski-Déri system will be employed.

TRAIN LIGHTING.—It is announced that the Canada Atlantic Railway Company will shortly introduce incandescent electric lighting in their passenger cars.

PERSONAL.—We are informed that Mr. Percy R. Allen has resigned the position of manager to the Woodhouse and Rawson Electric Manufacturing Company.

SUBMARINE CABLES.—The cable of the Paris-New York Telegraph Company, which was interrupted in the early part of August, has now been repaired.—The cable between Trinidad and Demerara is interrupted.

TYNEMOUTH.—At a special meeting of the Tynemouth Town Council, held this week, it was decided to accept the tender of the Gülcher Electric Light Company for providing electric light for the market place, amounting to £912.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.—We would call the attention of our readers to the information which will be found in our advertisement columns concerning the curriculum of this important college. The session commences on Monday, October 3rd.

ATLANTIC CABLE REPAIRS.—We are informed that the 1869 cable of the Anglo-American Telegraph Company, which was broken in deep water on 9th November last, at a distance of 600 miles from St. Pierre, Miquelon, was repaired on the 12th inst., and is now working well.

TEMPORARY ARC LIGHTING AT BIRMINGHAM.—Messrs. Fowler, Lancaster, and Co., of Birmingham, are running a temporary installation of five Pilsen arc lamps in the streets of that town, in order to enable the contractor for the cable tramway to complete the work in time.

THE NEW YORK ELECTRICAL EXHIBITION.—The Exhibition to be held at New York under the auspices of the New York Electrical Society will be opened on the 28th of this month. Applications have been made for seven hundred horse-power to run 2,500 incandescent lamps, 200 arc lamps, and 300 motors.

POST OFFICE TELEGRAPHS REVENUE.—The revenue returns for the half year ended Sept. 10, 1887, show that the total receipts into the Exchequer from the telegraph service between 1st April and 10th September was £905,000. Compared with the corresponding period last year there has been an increase of £65,000.

LYONS.—The gas company of this town has entered into a contract to supply electric light to the municipal theatres on the same scale and at the same price as gas. In return for this the company has obtained the right to lay underground cables through the streets. A central lighting station will be immediately established.

PERSONAL.—We are informed that, owing to pressure of business in other directions, Mr. Dowsing has found it necessary to retire from the membership of the firm previously known as Messrs. Thompson, Dowsing and Rew. The business will be conducted as heretofore by the remaining partners, under the style of "Thompson and Rew."

TELEPHONIC CONTRACTS OPEN.—On the 26th instant the telegraph department in Madrid will adjudicate a contract for the establishment and working of the telephonic lines in Vigo, and on the 27th instant for the telephonic lines in Granada. Particulars can be obtained from the director of the telegraph department, No. 8, Calle Claudio Coello, Madrid.

TELEGRAPH STORES REQUIRED.—The Great Western Railway Company are open to receive tenders for the supply of telegraph material, including instruments, poles, and wire. Samples may be seen on and after the 19th inst. at the office of the storekeeper, Paddington Station. Specifications and forms of tender may be obtained at the office of the storekeeper at Paddington or Swindon Stations. Tenders will be received up to October 3rd.

DANISH TELEGRAPHS.—The report of the Danish Telegraph Department for the year 1885 has just made its appearance. The country contains—or did contain in 1885—347 telegraph offices, 6 new stations having been opened during the year. The number of messages amounted to 714,286, which represents 36 per 100 inhabitants. There are four public telephone offices. Communication is still maintained in some parts of Denmark by semaphore signals.

ELECTRIC TRACTION BY ACCUMULATORS.—The *Bulletin Technologique* for September (issued by the Société des Anciens Eléves des Ecoles Naturales d'Arts et Métiers) contains a remarkably interesting paper by M. Bandsept on electric traction by accumulators, as exemplified on the Brussels tramways. We regret that in the present crowded state of our columns, we do not see any immediate chance of reproducing the article, which is of considerable length. Those, however, who are specially interested in the subject should not fail to read M. Bandsept's paper.

TAMPERING WITH RACING TELEGRAMS.—At the Bow-street Police Court Henry Wilkes, a clerk in the Central Telegraph Office, was charged with having tampered with a telegram by altering the order of the words. The telegram contained the names of the horses starting for a certain race, and it was alleged that the prisoner had detained the message until the result of the race was received, and had then made the alteration described, it being implied that in this way information was conveyed to the addressee enabling him to bet upon a known result. The prisoner was remanded for a week.

ELECTRIC LIGHTING IN MINES.—In the House of Commons on Monday last Mr. Matthews, answering Mr. Kelly, said he was aware the electric light was very little used in mines, but he looked forward to that light as being likely to form the best safeguard against explosions. He had seen various lamps which made him sanguine that some lamp which would satisfy practical requirements would shortly be invented, if the problem had not been solved already. He should use all the means in his power to induce the colliery proprietors to use this class of lamp, and he was glad to hear that the miners' delegates would use their influence in the same direction.

ELECTRICAL TREATMENT OF SILVER ORE.—At Douglass Mill, Dayton, Nevada, a method of treating silver ore by the aid of electricity has been brought into operation by Dr. J. H. Doe. The description given is by no means clear, but it appears that a current is passed through the ore while being treated with mercury in the crushing mill, with the result that an immense saving of mercury is effected. At Douglass Mill 135 tons of ore are worked per day, and it is stated that after two months' trial the economy effected is at the rate of £12,000 per annum. It is for this reason that we allude to the subject with only the present obscure account before us. Several new machines are being erected at neighbouring works.

INSULATED WIRES ON THE BROOKLYN BRIDGE.—A very large number of telegraph, telephone, and electric light wires

Digitized by Google

pass over the Brooklyn Suspension Bridge, and some trouble has arisen from their insulation. At first the wires were laid in iron pipes, but the average American insulation is not good enough for this simple method. Wooden cleating was next tried, but the damp salt sea air saturated the wood, and serious trouble again arose. Next the wires were supported on glass insulators, extending some distance away from the iron structure. This has answered for the smaller wires, but difficulty was still found with the electric light cables which supplied the arcs upon the bridge itself. Finally, these wires were covered at all joints and connections with a special insulating paint supplied by the Standard Paint Company, and this appears to have proved a remedy for the evil.

THE LIGHTING OF THE CITY OF LONDON.—The negotiation between the Commissioners of Sewers and the Anglo-American Brush Corporation for the lighting of a portion of the City still hangs fire, although there is good reason to expect that an agreement will eventually be arrived at. Meanwhile, in order to lose no time unnecessarily, the corporation are applying to certain of the vestries through whose jurisdiction the mains will pass for powers to take up the streets. The present intention is to generate current at the company's works at Belvidere-road, Lambeth, and to carry the cables along Stamford-street and over Blackfriars Bridge. The Vestry of St. George-the-Martyr, before whom an application of this nature came on Tuesday last, appeared somewhat inclined to deal with the matter in a hostile spirit, although apparently only about fifty yards of their roads, are affected. Eventually, however, the matter was referred to the Roads Committee.

THE THOMSON-HOUSTON FACTORY AT LYNN, NEAR BOSTON.—*Apropos* of the recent visit of the members of the National Electric Light Association of America to the works of the Thomson-Houston Company, at Lynn, the *Electrical World* remarks that the establishment is one of the largest of the kind in the world. At the present time over 700 men are employed, and the new wing about to be built will more than double the productive capacity. Some idea of the magnitude of the work may be formed from the fact that the arc light department can turn out 300 lamps weekly and is now in full blast. The factory building, which is four stories high with a floor space of about 80,000 square feet, requires some 450 h.-p., is lighted by 120 arcs and 300 incandescents, heated by steam, and is furnished with ample water from artesian wells on the premises. The visitors were conducted over the whole of the works, and were even allowed to witness the art and mystery of the manufacture of incandescent lamps in all its stages.

RULES FOR FIXING OVERHEAD WIRES IN NEW YORK.—The Board of Electrical Control in New York recently issued a set of rules regulating the construction of overhead wires in the city, "pending the providing of underground accommodation." Some of the clauses have, however, since been referred to an electrical engineer for revision. The important provisions are those limiting the lines of poles to but one on each side of a street or avenue, for similar electric service. The poles for electric lights are to be 20ft. high, and at least 8in. in diameter at the base; and of iron, with wood cross-arms. Other poles to be at least 60ft. high. All poles to be at least 10ft. from any lamp-post or other pole; and all poles, new and old, to be plainly marked with the initials of the company owning them. No arc electric light or power wires are to be strung over any portion of a house or building. No new wires to be stretched in streets where conduits are, or are being provided. There are also provisions limiting the time that poles may lie upon the ground before erection.

MANUAL TRAINING IN ELEMENTARY SCHOOLS.—An admirable paper on this subject was read at the British Association meeting by Mr. Mather, M.I.C.E., and which bears out entirely the views on technical education frequently advocated in this journal. The training he proposes is neither for any particular handicraft nor in any special branch of science, but is designed to teach children how to observe, how to use, and how to create. The only manual instruction, the author points out, that is given by our national school system is in handwriting; and Mr. Mather, who is a large employer of persons educated under this system, speaks of it as an utter failure—boys who have attained high distinction in the schools often betraying complete dormancy of the constructive faculty. The system advocated by Mr. Mather, and for the particulars of which we must refer our readers to the paper itself, is becoming very popular in the United States, where some very remarkable results have already been obtained. We regret to notice that the idea was not well received at Manchester.

THE CHARTERHOUSE SCIENCE AND ART SCHOOLS.—The Winter Session of this, one of the largest Science and Art Schools in the United Kingdom, will commence on Saturday, October 1st, 1887, under the presidency of the Rev. Henry Swann, M.A. During the late session about 950 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number upwards of 650 presented themselves for examination, and were successful in obtaining a large number of first class certificates and also a goodly number of first and second class honour certificates awarded by the Science and Art Department of South Kensington. Of eight students prepared for the Lond. B. Sc. (Int.) examination, only one student failed; the others highly distinguished themselves. Instruction of a practical character is given in most of the sciences at a very nominal fee; whilst in art, at an equally low rate, students, under the direction of five competent instructors, can be advanced in their studies. Both day and evening classes are held, full particulars of which may be obtained from Mr. C. Smith, organising secretary.

MEETING OF THE ASSOCIATION OF EDISON ELECTRIC LIGHT COMPANIES.—The fifth semi-annual convention of the Association of Edison Electric Light Companies of America has just been held at Altoona, when the following resolutions were carried: That in consequence of the fact that "Underwriters'" wire, so-called, has been shown by experience to be unreliable and treacherous in its action, we regard it as introducing injurious possibilities in all interior wiring; we discountenance its use and urge upon the attention of the companies composing this association the desirability of abolishing it entirely in the work of wiring buildings over which they severally exercise a control. That we extend to the Edison Electric Light Company our cordial and moral support, and an assurance of our conviction that the present unprincipled rivalry now affecting some of the local companies here represented will be speedily terminated by decisions in favour of the Edison patents, thus bringing to justice all who have ignored the rights granted by the patent laws of the United States to the Edison Company, as the heirs of Mr. Edison's electric light invention.

ELECTRIC TRACTION IN MINES.—The employment of electric traction in mines, although one of the earliest permanent applications of electric motors (of large size) in Europe, has somewhat singularly only now received its first illustration in America. The Short Mountain Colliery, in Pennsylvania, has just been furnished with plant for working an underground line about one mile in length. The line has several steep gradients and some sharp curves; it has, however, been found prac-

Digitized by Google

ticable to adopt a relatively high rate of speed, and with a train of 10 mine waggons, representing a total weight of nearly 50 tons, it is stated that the distance is run in six minutes, or at the rate of ten miles an hour, the motor being rated at 25 horse-power. The current is taken off from a third insulated rail. By mule-power, previously employed, half an hour was occupied in the same amount of haulage. The contract was carried out by the Union Electric Company, who have put in a steam engine capable of developing 130 horse-power, believing that the system will shortly be extended to other parts of the mine. This example is certain to be extensively followed in the States.

THE PYRO-MAGNETIC MOTOR.—In our issue of August 26th, 1886, will be found an account of a simple experiment by M. Schwedoff, in which the direct conversion of heat into mechanical motion by the aid of magnetism is illustrated. M. Schwedoff takes a small ball of iron and suspends it by a wire in front of a Bunsen flame. He then brings a magnet to the other side, the ball is attracted, moves into the flame, loses its magnetic power and retreats, cools down, and is again attracted, and so on; work being done at the expense of the heat of the flame. The same phenomenon was, however, demonstrated at a still earlier date, and perhaps more effectively, by Profs. Houston and Elihu Thomson. The *Journal* of the Franklin Institute for 1879 contained a description of this experiment. A thin disc of wrought iron was mounted on a spindle and placed between the poles of a horseshoe magnet, with its plane parallel to the lines of force. If now a portion of the disc be heated the attraction of the magnet upon the opposite side is unbalanced, and a slow rotation ensues. This early reference is referred to in a letter by Carl Hering in the *Electrical World*.

MAGNETISM AND MORPHOLOGY.—Some experiments have been placed on record—we forget for the moment by whom—in which a number of eggs were hatched out in a magnetic field, with the result that the chickens were all more or less deformed; blind, deaf, or lame. A biologist at Manchester, in course of conversation, told us that he had several times tried to repeat the experiment, but with the result that the eggs were always addled. Without professing to expound the physiological or morphological reasons for these singular results, it is at least permissible to suppose that the movements of the protoplasmic substance in the magnetic field set up currents of electricity, which tend to decompose the delicate organic structures of the egg so as to destroy or vitiate its vitality. We recommend the study of this very interesting question to the people of Southsea and the neighbourhood, who we learn are continuing to derive unspeakable advantages from a frequent resort to Captain Arthur H. Byng's patent electrified rooms. So successful has been the original company, that it has recently been reconstructed with a view to extending its operations to London and other large towns; in fact, we hear that its advent in the West End may shortly be expected.

LIGHTNING CONDUCTORS.—The following letter from Prof. Tyndall appeared in *The Times* on Tuesday last:—"The question of lightning conductors needs further ventilation. The letter which you allowed to appear in *The Times* of August 31 has brought me ampler proof of the ignorance or carelessness sometimes displayed by architects and builders in relation to this question. Various applications have reached me regarding chimney stacks and edifices to which lightning conductors, *minus* the absolutely necessary earth-plates, have been attached. To such applicants for advice I would reply practically by saying that my own house in the country is provided with conductors manufactured and set up by Mr. Anderson, of the firm of Sanderson and Co., Leadenhall-street—introduced to me by the late excellent Dr. Mann, who had devoted much attention to this special subject. Other workmen equally good are, I doubt not, to be found, but accident or good fortune threw Mr. Anderson in my way, and with his work I am thoroughly satisfied. I may add that the sums set apart by architects and builders for the erection of conductors are often totally inadequate to cover the cost of them. Scant provision on this score may be one reason for omitting the terminal plates, and thus failing to provide a safe earth connection."

MR. TROTTER'S METHOD OF REGULATING DYNAMOS FOR CONSTANT CURRENTS.—It is at all times a somewhat ungracious task, when an independent discovery or invention has been made, to have to point out that it belongs to the wide category of things true but not new. Yet in the interests of historical accuracy it is a task which we are frequently obliged to perform. This is the case with regard to Mr. A. P. Trotter's very beautiful method of "maintaining constant current with varying electromotive force from a dynamo," which was described before the British Association on the 4th September, and appeared in our columns last week. The following paragraph is taken from a supplement issued with this journal on the 31st July, 1885, and was written by Mr W. M. Mordey:—"There is another plan, one which has found several advocates, amongst them Edison. According to this it has been proposed to vary the field, not by alteration of the magnetising current, but by having a non-magnetic gap in some part of the magnet, usually the yoke, which gap could be filled to the required extent by a movable iron plug playing the part of a variable 'magnetic resistance;' or by placing a 'keeper' on the poles which acted as a magnetic shunt on the armature, in the manner familiar to us in the magneto-electric stocking or 'medical' coils to vary the power of the field-magnet." We are not, however, aware of any successful application of this principle prior to its re-invention by Mr. Trotter.

CARBON AS THE POSITIVE ELEMENT IN A PRIMARY BATTERY.—A new primary battery has been devised by Mr. Willard Cease, of Auburn, in which carbon is consumed in chloric acid, the negative element being platinum. The E.M.F. of the cell is 1·25 volt. From the highly explosive character of the substances employed it is evident that the cell cannot have more than a theoretical degree of interest. The arrangement adopted by Mr. Cease is the following:—Crushed carbon moistened with sulphuric acid is placed in a porous pot, surrounding a carbon plate to which a terminal is affixed. Strong sulphuric acid is placed in the outer cell together with the negative platinum element. To the acid chlorate of potash is added in small quantities; peroxide of chlorine (ClO_2), which dissolves in the acid, gradually producing a yellowish red coloration. This solution of chloric and sulphuric acid is, as is well known, one of the most powerful oxidising agents that can be prepared. As soon as the solution has percolated the porous jar the carbon is attacked with the formation of carbonic dioxide, and an E.M.F. of 1·25 volt is set up. The cell should be kept in the dark and at a low temperature. At 140deg. F. peroxide of chlorine explodes with violence, and exposed to sunlight it is decomposed. A drop of this liquid touching the skin leaves a nasty wound. The cell polarises to a certain extent. The action can of course be obtained in a single cell and with a simple carbon plate, but the action is quieter and more steady when a porous pot is used.

THE ARMINGTON-SIMS ENGINE.—Messrs. Greenwood and Batley, of Leeds, send us an extract from a pamphlet issued by

Digitized by Google

the Edison Electric Light Company, New York, entitled "The Edison System of Central Station Lighting," in which the Armington-Sims engine is referred to in very flattering terms. "In the early history of our business," says this Company, "it was discovered that high speed is essential to steadiness of light, and all the best known engines in the market were thoroughly tested. Several were found fairly well adapted to running dynamos in isolated plants, but there was nothing that would run successfully in multiple arc, *i.e.*, where two or more engines were operating dynamos delivering their current into one common main or conductor. This is a condition existing in all our central stations, and one which no other company has as yet been able to acquire. In order to supply this urgent need, Messrs. Armington and Sims, of Providence, R.I., made what is known as the 'Armington and Sims' engine, which was partly evolved from the best points of several of the best engines then in use, but with entirely original and distinctive features, specially designed to meet our particular requirements. It is a horizontal high-speed, short-stroke, automatically variable cut-off engine, with a balanced piston valve, compactly built, perfectly balanced, and in the matter of strength is constructed with special reference to withstanding the strain of the high speed at which it is run. As is well known, the engine was eminently successful, and has given great satisfaction everywhere. There are now in use, in connection with Edison dynamos alone, about 300 of those engines, and our experience with them compels us to endorse them as the only engines that have been thoroughly tested for central station work."

Opposition to Electric Light at Leamington.—A memorial to the Local Government Board, it is stated, is being prepared, praying that the application of the corporation for a loan to provide the "fixtures" for the electric light may not be granted. The memorial states: 1. That, in the opinion of the memorialists, the proposal by the corporation to light the principal streets and principal buildings of the town of Leamington by electricity is wholly unnecessary, and will be productive of considerable expense without any corresponding benefit. 2. That as a street illuminant the incandescent lamp, which is the one proposed to be used in Leamington, has been used in London and other towns, and has, they believe, in nearly all instances been abandoned. No inquiries have been made by the council on this head. 3. That the Midland Electric Light and Power Company (Limited), which is the company executing the works in Leamington for the supply of electricity, has obtained no license or provisional order from the Board of Trade, in pursuance of the Electric Lighting Act, 1882, to light the town, and is consequently put under none of the regulations and conditions mentioned in Section 6 of such Act. 4. That only some two years since the corporation expended a sum of £250 in new gas fittings in the town hall, all of which it is now proposed to do away with, and to expend therein £479 in fittings for the electric light. 5. That no agreement whatever has been come to with the council and the Midland Electric Light Company with reference to the method of supplying the electricity beyond what took place in a conversation between the representative of the company and the council, and which has already been broken as regards the time in which the electricity was to be supplied. In the event, therefore, of the light not being a success, the money now proposed to be expended will be thrown away. 6. That gas is exceedingly cheap in Leamington, the price to the public lamps being only 2s. 7d. per 1,000ft. And, therefore, the memorialists are of opinion that the proposed scheme of lighting the streets and public buildings with electricity will be detrimental to the interests of the town, and they pray the Local Government Board not to sanction the loan applied for for this purpose.

The Telephone, the Railway Companies and the Post Office.—The Western Counties and South Wales Telephone Company have long been wishful of establishing a public call office at the Bristol Joint Railway Station. Negotiations were commenced on October 14th, 1886, but have as yet led to no result. The nature of the obstacles existing may be gathered from the following copy of a memorial to the Postmaster-General, which has been signed by the president and officers of the Bristol Chamber of Commerce :—

To the Right Hon. H. C. Raikes, M.P., Her Majesty's Postmaster-General.

The humble memorial of the Bristol Incorporated Chamber of Commerce and Shipping showeth, that your memorialists learn that a telephone call office has been erected at the Bristol Joint Railway Station for the convenience of subscribers to the Western Counties and South Wales Telephone Company, who may arrive at or depart from the station, or who may desire to communicate with their offices or other subscribers, but that unfortunately the said office has not been opened, in consequence of a difficulty having arisen between your department, the telephone company, and the Great Western Railway Company. Your memorialists are informed that the railway company object to sign an agreement with your department on the ground that your department have no exclusive rights on the station property. Whereas, on the other hand, should the office be opened without this agreement being duly executed, your department threaten that the general license of the telephone company for the whole of their district would be cancelled. That on reference to a letter from your department, dated 4th June, 1887, addressed to the secretary of this chamber, in reply to an inquiry as to whether your department would offer any objection to the opening of call offices by that company, it was stated that, under the license of the Postmaster-General, the company were permitted to establish exchanges and call offices in any town in the United Kingdom without obtaining any further consent from your department. That your memorialists much regret that the call room still remains unopened, as it would be a great convenience to the public, and they are of opinon that the general license of the telephone company ought to cover the opening of the said office. Your memorialists therefore humby pray that your department will be pleased to remove the obstacles in the way of the use of the said telephone call office.

Nobili's Rings and Allied Electro-Chemical Phenomena.—Herr Elsas (in the *Ann. Phys. Chem.*) expresses the opinion in opposition to Voigt, that Nobili's rings are mainly due to currents which traverse the electrolysed liquid nearly parallel to the metal plate. The colours obtained are not in all cases colours of thin plates; but the rings are sometimes deposits of different chemical and physical constitution. In fact, electro-chemical decomposition takes place not only at the surfaces of the electrodes, but at every point throughout the liquid traversed by the current. This is proved as follows. Plaster of Paris moistened with copper sulphate solution is poured on a metal plate, and a copper wire plunged into the still soft mass with its end very close to the plate. The plaster is allowed to set firmly, and a current is passed from wire to plate. On removing the cake, four or five coloured rings are seen on its surface, corresponding rings being found on the plate. The plaster also adheres to the metal more or less firmly in different zones, and is also distorted. The central area opposite the wire is green (CuH_2O_2?), and is surrounded by rings successively white, blue, white, red (Cu) and again blue. When the current is long continued, coloured deposits are also found throughout the mass of the gypsum. The

Digitized by Google

colours of the rings are independent of the nature of the metal plate, when the latter does not directly act on the electrolyte. When the anode wire is of platinum, the electrolyte becomes acid and pure copper is nowhere deposited. When it is of iron, rust-coloured rings are found in the gypsum plate, showing that transference of the ions takes place even in the solid. If the metal plate is made the anode, a blue circle appears round the cathode, surrounded by an intensely blue ring. When a current is passed between two wires immersed in a plate of gypsum, prepared as above on a plate of glass, circular coloured rings are formed round each wire. The isochromatic lines do not correspond either with the equipotential lines or the lines of equal current-intensity. If in this experiment a metal plate is substituted for the glass, rings also appear on its surface. These appear to coincide with the equipotential lines only at some distance from the wires. Theoretical views follow as to the distribution of potential in the last case. But the appearances cannot be explained by reference to this alone, as Guébhard imagines.

ELECTRIC COMMUNICATION WITH LIGHTSHIPS. — The report of the committee appointed by the Board of Trade to inquire into the desirability of establishing electric communication between lightships and the shore has just appeared. The evidence went to demonstrate in a most conclusive manner that the value and efficiency of the life-boat service would be vastly increased by the establishment of electric communication. Numerous cases were quoted in which vessels have been wrecked within sight of the lightship, while the weather has been so thick that much valuable time—sometimes many hours—has been lost before the attention of the life-boat station could be attracted. In other cases where lightships are stationed not far apart, the difficulty of telling from which ship the sound of the signal guns proceeded has taken the life-boat in the wrong direction and led to loss of life. All this would clearly be prevented if the lightship were electrically connected with the shore. Nevertheless, the committee report that this is "not desirable" on account of the expense, though they recommend that the experiments which have been carried out during the last three years between the town of Walton and the "Sunk" lightship off the Naze should be continued for another eighteen months. It should be explained that the object of the committee is to endeavour to arrive at the most economical system for general adoption, which, notwithstanding the wording of the report, they fully recognise to be eminently desirable. The experiments at the Naze, although perfectly successful electrically, have yet so far proved extremely costly. The experience obtained has shown that the telephone is the most suitable instrument for maintaining communication. With a receiver at each ear no difficulty is experienced in hearing even in the loudest gale. The length of cable employed is nine knots with an earth return. Daily electrical tests were made showing an insulation resistance in winter of 1,519 megohms, and 172 meghoms in the summer. The resistance of the copper conductor was 0·77 ohm in the winter and 0·81 ohm in the summer. The inductive capacity was about 3·2 microfarads. The temperature of the sea bottom was in winter 44deg. F., and in summer 62·5deg. F. The work was carried out by the Telegraph Construction and Maintenance Company, who have devoted much energy and attention to overcoming the mechanical and electrical difficulty of connecting the ship so as to permit of perfect freedom of motion without danger of fouling the cable.

THE ELECTRIC CURRENT AS A MEANS OF INCREASING THE COEFFICIENT OF FRICTION OF ROLLING CONTACTS.—Many years ago a series of experiments were carried out upon a line of railway in America in order to determine whether it was possible to increase the tractive force of a locomotive by magnetising the tyres. The conclusion arrived at was an unfavourable one, and the experiments led to nothing. The subject has, however, been again taken up by Mr. Elias E. Ries, and in a paper read before the American Association for the Advancement of Science he gives some very interesting information on the subject. The increase in the tractive force of electric tram or railway cars taking off current from the rails has often been claimed as a feature of the system, but no very definite observations have hitherto been made. Mr. Ries is conducting a series of careful experiments of this nature, which are not yet completed, but he is able to state that an electric current traversing a rolling contact increases the tractive adhesion in some cases as much as 50 to 100 per cent., the increase depending on the nature of the substances in contact and increasing with the current. "These experiments," he says, "were originally directed mainly towards an endeavour to increase the tractive adhesion of the driving wheels of locomotives and other vehicles, and to utilise the electric current for this purpose in such a manner as to render it entirely safe, practical, and economical." The best results are obtained by the use of an alternating current of large volume furnished by means of a transformer supplied with a current of higher potential in the primary. It does not, however, appear that the employment of an alternating current is essential to success. One of the driving wheels is insulated from the axle—a matter which, as Mr. Ries states, presents no difficulty—the current passes into this wheel through a brush bearing on the axle, reaching the rail it enters the second pair of wheels, by which it crosses into the opposite rail, and thence, through the remaining wheel and a second brush, it returns to the generator, so that the current traverses the rolling contact of all four wheels. This is Mr. Ries's description of the circuit, but it would seem necessary to insulate the frame either from the wheel with which the second brush is connected, or else from the second pair of wheels; otherwise one of the rails would practically be short-circuited. An E.M.F. of from 0·5 volt to 1 volt only is required, but the current does not appear to have been measured. It will be seen that the arrangement is a perfectly safe one, as only that portion of the rails which lies at any moment between the two pairs of driving wheels is included in the circuit. The arrangement need not of course be always in use; if desired its employment can be restricted to the ascent of heavy gradients, when the rails are in a particularly slippery state, or for especially heavy loads. A different and probably better method of attaining the same result has also been devised by Mr. Ries. This consists in magnetising the axle or axles of the driving wheels by means of a coil surrounding the shaft. A closed magnetic circuit is thus established through the wheels and rails. A model car, fitted with this arrangemeent, was exhibited, and by means of a dynamometer it was shown that the tractive force was increased nearly 200 per cent. when the circuit was closed. The model car was able to ascend a gradient of 1 in 3, and easily remained at rest upon an incline of 1 in 2½ when the motive power was shut off. It even required considerable force to push it down this incline, while without the magnetic arrangement it was of course unable to maintain its position. It is further obvious that the same principle can be applied to the brakes. This idea has been carried out in a very simple and ingenious way by Mr. Ries. The brake shoes are ordinarily held off from the wheel by being magnetised in the same direction. On the reversal of the current in one of the coils the shoe is strongly attracted, constituting a very powerful brake.

ON A PRACTICAL METHOD OF MEASURING THE COEFFICIENTS OF SELF AND MUTUAL INDUCTION.

BY GUY C. FRICKER.

Since the development of alternating current dynamos and of distribution by means of induction coils,* a number of methods for determining the coefficients of self and mutual induction have been devised.

For the most part these involve operations of too delicate or laborious a character to find favour with practical electricians.

It is true that the method described by Mr. T. H. Blakesley,† whereby the coefficients L and M may be found by aid of certain observations on a Siemens dynamometer, is a distinctly practical and excellent one, involving the use of no special apparatus. A slight modification in the usual arrangement of the instrument is, however, essential to it.

It occurred to the writer that the known relations between the angle of retardation of the current and the impressed force, so conveniently expressed by Mr. Blakesley's diagrams, would furnish sufficient data for another, and perhaps in some ways, a still more convenient method of determining L and M than that given in his book.

The procedure is as follows:—

Single Circuit.—Take on open circuit the reading of a Cardew voltmeter giving ·707 E, where E = the maximum value of the impressed E.M.F. Denote this by the line A B in Blakesley's triangle (Fig. 1) and call it a.

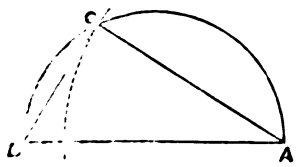

FIG. 1.

Next close the circuit through a non-inductive resistance, and adjust the same until a certain current, which should be large, is indicated on a Siemen's dynamometer, and take a second reading, β, on the voltmeter.

The dynamometer measures $\frac{I^2}{2}$, where I is the maximum value of the current; thus

$$I = \sqrt{2 \times \text{dynamometer reading}} = \sqrt{2C}.$$

Then if r is the internal resistance of the dynamo, $r\sqrt{2C} + \frac{\beta}{\cdot 707}$ = the maximum value of the effective E.M.F., which call h.

On A B as diameter describe the semi-circle A B C, and from the centre A at the distance h describe an arc cutting the semi-circle A B C in the point C; join A C,

then $$L = \frac{RT}{2\pi} \tan B A C,$$

where R is the total resistance of the circuit and T is the periodic time.

Two circuits.—Place the voltmeter in the secondary circuit, otherwise open, and pass a current of maximum value, I_1, through the primary. The current indicated by the dynamometer can be called C_1.

The reading on the voltmeter then gives ·707 × the maximum value of the impressed E.M.F. on the secondary, and is represented in the diagram (Fig. 2) by the line C E.

At right angles to C E set off C F, equal to $I R_1$, where R_1 is the total resistance of the primary circuit, and join F E;

then $$M = \frac{R_1 T}{2\pi} \tan C F E.$$

Next, keeping the primary current constant, take the dynamometer reading $\frac{I_2^2}{2} = C_2$ in the secondary, and also a second reading (γ) on the voltmeter. Then, as before, $\frac{\gamma}{\cdot 707} + R_2\sqrt{2C_2}$ = the effective E.M.F. in the secondary, where R_2 is the resistance.

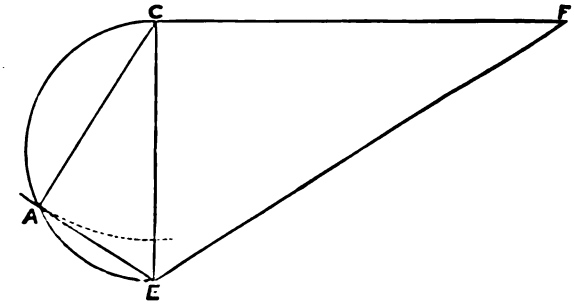

FIG. 2.

Setting this out within the semi-circle C A E the angle A C E is obtained, and if L_1 = the coefficient of self-induction in the secondary

$$L_1 = \frac{R_2 T}{2\pi} \tan A C E.$$

To find L in the primary the circuits are reversed.

It is evident that the formula $\frac{RT}{2\pi} \tan \phi$, where ϕ is the angle of retardation, must be a constant, and therefore independent of the current.

For in the triangle A B C the effective E.M.F. $E \propto \cos \phi$ and the E.M.F. of self-induction $E_1 = I L = \frac{E}{R} L \propto \frac{L}{R} \cos \phi$.

Also, $$\tan \phi = \frac{E_1}{E} \propto \frac{L}{R};$$

$$\therefore R \tan \phi \propto L.$$

* This point will be dealt with in its proper place in the articles on "Dynamo Design"; but in view of the interest attaching to all questions relating to distribution by alternating currents, it has been thought that the following might well appear as an advance note.

† See *Electrician*, Vols. XIV. and XV.

ON THE CONDITION OF MAXIMUM WORK OBTAINABLE FROM A GIVEN SOURCE OF ALTERNATING E.M.F.*

BY GISBERT KAPP.

The following investigation applies to all cases where the whole of the work is done in the circuit which receives current from some source of supply having an impressed alternating E.M.F., but it does not apply to those cases where the E.M.F. is impressed on a primary and the work is done in a secondary circuit. As an example, take the case of glow or arc lamps fed in parallel connection direct from two mains between which is maintained an E.M.F. alternating according to a simple sine function. We assume the mean value of this E.M.F. as measured by a Cardew voltmeter or a Thomson electrometer to be maintained constant whatever may be the quantity of current taken by the different lamp circuits, and the periodic time of the wave of impressed E.M.F. to be also constant.

We also assume that each parallel contains a portion having a sensible self-induction, and the problem is to find what resistance should be given to the lamp in order to use up or rather transform in it a maximum of energy with the given impressed E.M.F. With a unidirected and constant E.M.F. the lower the resistance the greater would be the energy used up in the lamp; but this is evidently not so in the case of an alternating E.M.F., since upon short-circuiting the lamp completely the current does not exceed a certain maximum—which is determined by the self-induction of the circuit—and during a gradual reduction of resistance of the lamp, the current, being one of the factors determining the work, remains therefore finite, whilst the other factor (the E.M.F. over the lamp terminals) approaches zero. A maximum of work can there-

* Paper read before the British Association Meeting, at Manchester, September, 1887.

Digitized by Google

fore not be obtained by the simple expedient of reducing the resistance of the lamp to its lowest possible value. That an excessive increase of resistance will not accomplish the desired effect is self evident, and we are thus led to the conclusion that between these extreme values of resistance there must be at least one special value for which the work done in the lamp becomes a maximum. The value of this particular resistance must naturally depend upon the E.M.F. of supply, the periodic time, and the self-induction of the circuit.

Before proceeding further it will be convenient to point out that the same consideration applies to a circuit fed from the secondary coil of a transformer, the primary coil of which is connected in parallel across the mains from an alternate current machine. In this case the E.M.F. appearing on the terminals of the secondary is very nearly constant if the E.M.F. between the mains is kept constant, a condition which must necessarily be fulfilled in a network of mains for public supply of electricity on the parallel system. We may therefore consider the E.M.F. induced in the secondary coil as an E.M.F. impressed upon the terminals of the circuit in which the work is to be done, and thus our problem becomes applicable both to the direct supply and to the supply by means of transformers.

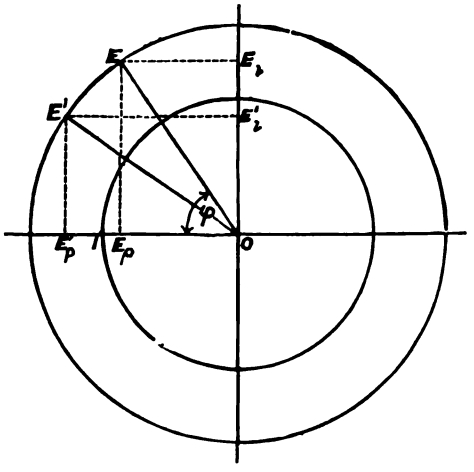

FIG. 1.

Let in the diagram O E = E represent the impressed E.M.F., and O I = I the resultant current, both being maxima—that is, the crest of their waves—and let ϕ be the angle of lag. The maximum value of the E.M.F. due to self-induction is then obviously given by the line $\overline{O E_\iota} = E_\iota$, and the maximum of E.M.F. necessary to overcome the inert resistance of the circuit is given by the line $\overline{O E_\rho} = E_\rho$. If r denotes the resistance and L the self-induction, we have $E_\rho = r I$, and $E_\iota = L I 2\pi n$. The angle of lag, as is well known, is determined by the relation

$$\tan \phi = \frac{2\pi n L}{r}.$$

We may now represent the impressed E.M.F. and the resultant current at any moment, as the projections of the two lines O E and O I on the vertical, these lines being supposed to revolve round O at a fixed speed, and to always maintain their angular distance ϕ. Let α be their angular advance at the time t, then $e = E \sin(\alpha + \phi)$ and $i = I \sin \alpha$ represent E.M.F. and current at that particular moment, and

$$d W = E I \sin(\alpha + \phi) \sin \alpha \, d t$$

represents the work done during a further angular advance during time $d t$. If $T = \frac{1}{n}$ be the periodic time $\alpha = 2\pi n t$, and the above equation can also be written as follows:—

$$d W = \frac{E I}{2\pi n} \sin(\alpha + \phi) \sin \alpha \, d \alpha.$$

By integrating between the limits $\alpha = 0$ and $\alpha = 2\pi$, we obtain the work done during the time T (that of a complete period), and by dividing the result by T we obtain the work done in unit time, or the rate of doing work as generally expressed in watts. The operation gives

$$W = \frac{E I}{2} \cos \phi \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Since the mean value of E.M.F. and current measured by instruments is $\frac{1}{\sqrt{2}}$ of their maxima, we have also

$$w = e i \cos \phi,$$

e and i being these mean values. This expression enables us to determine the work done from readings taken with a voltmeter and a current dynamometer, provided we know the resistance of the circuit. From the diagram it will be seen the angle of lag is found by the formula $\cos \phi = \frac{i r}{e}$, and substituting we obtain $w = i^2 r$, which is self-evident. This result might have been obtained without introducing the E.M.F. at all; but, as will be shown presently, the investigation applies also to cases where, besides an inert resistance, there is a counter E.M.F. in the circuit, and then the term $i^2 r$ is not a correct measure for the work done, and the more general expression given in equation (1) must be used.

From a commercial point of view it is important that the lag should be small, because the size of the dynamo and mains is governed by the product E I, whilst the work done by the dynamo is governed by the product $\frac{E I}{2} \cos \phi$, and it is evident that if ϕ be very nearly 90deg. we would require an enormously large plant to do comparatively little work. Generally speaking, the size of the plant for a given amount of work will be inversely proportional to cos ϕ. In a continuous current system there is no lag, and the whole volt-ampere capacity of the plant is actually available for useful work; in an alternate current system this capacity becomes reduced in the ratio of 1 : cos ϕ, and cos ϕ might therefore be considered to represent the plant efficiency of the system.

Returning now to the original problem we have to find the condition under which the work E I cos ϕ, and therefore I cos ϕ, becomes a maximum. From the diagram we see that E_ι or $2\pi n L I = E \sin \phi$, and therefore $I \cos \phi = \frac{E}{2\pi n L} \sin \phi \cos \phi$. To make this a maximum the angle of lag must evidently be 45deg. The same result has been found analytically by Mr. Snell, and published in his articles on "Alternating and Induced Electromotive Forces," in *The Electrician* of August 13th, 1886. Graphically, the projections of O E on the horizontal and vertical must have equal length—that is to say, E_ι must be equal to E_ρ. Maximum work is done in the circuit if the E.M.F. of self-induction equals the E.M.F. necessary to overcome the inert resistance. In this case the following relation must evidently obtain $r = 2\pi n L$, and by choosing the resistance so as to satisfy this equation we obtain a maximum of work from the given mean E M.F. e, and in a circuit of given self-induction L. The E.M.F. which is used to drive the current through this resistance is ·709 of the impressed E.M.F., and this figure represents also the plant efficiency of the system.

The above law of maximum work is capable of application to the case of a series-wound electromotor worked by an alternating current. An ordinary series-wound continuous current motor can be worked by an alternating current if the field is sufficiently laminated to prevent the formation of eddy currents. There are certain reasons which render it inexpedient and uneconomical to work any apparatus for the utilisation of alternating currents at high degrees of saturation, so that in practice the strength of field of such a motor can be considered as strictly proportional to the current at any moment. In a motor of this kind the flow of current is opposed not only by its inert resistance, but also by the counter E.M.F. developed in the coils of the armature. It is evident that at constant speed of rotation the latter opposing force is proportional to the strength of field, and therefore also to the current, and it is of the same character and period as the E.M.F. necessary to overcome the inert resistance of

Digitized by Google

the circuit. Retaining the above notation, and writing ki for the counter E.M.F. of the armature, where k is a coefficient depending on the constructive data of the machine and on its speed, but not on the periodic time and self-induction, we have at any moment $e_\rho = (r+k)i$, and the condition of maximum work is $r+k=2\pi n$ L. In order that the motor may absorb maximum work, it should be so constructed that the sum of the counter E.M.F. of the armature and the E.M.F. necessary to overcome its inert resistance equals the E.M.F. of self-induction. In order to obtain a high efficiency, r must be small as compared with k, and in this case we may as a rough approximation neglect r, and say that the motor will give out maximum work if its counter E.M.F. equals the E.M.F. of self-induction. This law has a striking resemblance to Jacobi's law of maximum work obtainable from a continuous current motor. There the condition is that the counter E.M.F. should equal the E.M.F. necessary to overcome the inert resistance of the circuit; but whilst in this case the commercial efficiency must be less than 50 per cent. in the alternate current system it may be much more. In so far the alternate current motor would seem to have an advantage over the continuous current motor, but this advantage could scarcely be realised in practice. On the one hand, we never work continuous current motors with maximum output, whilst on the other hand it will be found extremely difficult, not to say impossible, to work a series-wound motor by an alternating current of reasonably short period in such a way as to satisfy the above conditions for maximum work. It will generally be found that in a motor of this type, owing to the great magnetic inertia of the field, the E.M.F. of self-induction is considerably greater than the counter E.M.F. of the armature, and that to increase the latter without at the same time increasing the former we should require to run the armature at too high a speed. But even if we cannot completely fulfil the condition of maximum work we can at least attempt to approach it, and the above investigation may serve to show in what direction improvements should be made if we wish to solve the practical problem of obtaining motive power from alternating currents. In experimenting with machines of this class it is of course necessary to have some easy means for the determination of the coefficient of self-induction, angle of lag, and plant efficiency. These points can be easily determined by means of the diagram. Two experiments only are required. First, note the mean current and mean terminal pressure when the armature is prevented from revolving; and, secondly, note the mean current when the armature is revolving and doing work, the terminal pressure being adjusted to have the same value as formerly. Let, in the diagram, the line O E_ρ represent the E.M.F. required to overcome the inert resistance of the motor. This can be calculated from the known resistance and the measured current. By erecting a perpendicular in point E_ρ, and prolonging to the point of intersection with the circle representing the impressed E.M.F., we find the point E, the angle of lag ϕ, and the horizontal projection of O E gives O E_i the E.M.F. necessary to overcome self-induction. Since the latter is proportional to the current which has been measured, the coefficient of self-induction can now be determined. When the armature revolves, the current becomes reduced, and therefore the E.M.F. of self-induction assumes a proportionately reduced value, which in the diagram is represented by the length of the line O E'_i. To this corresponds the point E′ on the circle of impressed E.M.F., and projecting this point vertically we find E'_ρ as the E.M.F. necessary to overcome the counter E.M.F. of the armature and the inert resistance of the motor circuit. The latter can be calculated from the current and resistance, and thus the counter E.M.F. of the armature and the electric energy actually available for conversion can be determined.

TUNGSTIC ACID.—Eisenmann recommends the use of tungstic acid in primary batteries. Its chemical behaviour is very similar to that of chromic acid, but it has the advantage of being rapidly oxidised after reduction. In order to prevent the formation of a precipitate in the cell the addition of a small amount of phosphoric acid is desirable.

CORRESPONDENCE.

RULES FOR INSTALLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Is there any truth in the rumour we hear that electrical engineers are to have yet another burden laid upon them in the shape of another set of "rules," to emanate from themselves as represented by the Society of Telegraph-Engineers and Electricians. Surely we have enough to bear from extraneous sources without ourselves increasing our difficulties. We already possess a good set of rules, the correctness and completeness of which are of world-wide renown, even the United States, as well as the Continent, deigning to take a leaf out of our book by recognising the Phœnix Fire Office rules, of which English electricians ought to be proud. We ourselves have always worked in accordance with these rules, and although we have put up some of the largest installations in the country have never had the slightest trouble with the fire inspectors, even when we have had to meet the redoubtable Mr. Heaphy himself on installations where the fire risk in point of value involved is very large.

To our mind the Phœnix rules fulfil all requirements, and whatever new hobbies the above-mentioned society may see fit to perpetuate in their fruitless endeavours after notoriety, we are sure they will never attain the prestige or universal authority of the Phœnix rules; and speaking for ourselves we do not propose altering our system, and shall continue to specify in our contracts and to erect our installations in accordance with the Phœnix Fire Office rules. Within the last few days we have had practical experience of the trouble we are likely to encounter daily if the ridiculous action of the Society of Telegraph-Engineers be persisted in.—Yours, &c.,

14th September, 1887. ELECTRICAL ENGINEERS.

THE D'HUMY BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is a pity that your space is too valuable for the entire reproduction of the prospectus of "The Water Primary Battery Company (Limited)" and the press comments thereon, for I venture to say that documents more worthy of careful consideration and study it has seldom been my lot to examine. But since such be impossible, I trust that the following remarks and abstracts may in some way compensate your readers for the loss they have sustained in not being able to personally enjoy what is at once erudite and profound.

I will pass over the opening statement that "prior to the invention of *this* water battery it was deemed practically impossible to charge accumulators and store electricity with primary batteries" by expressing my astonishment at our general ignorance in not being aware of this fact before. At the same time it does not appear in what way *this* water battery has accomplished this feat, which the other water batteries failed over; we assume it *washed* away the difficulty. Possibly this great discovery was due to that eminent electrician—figuring in the prospectus—who one day assured me that an accumulator could be charged and discharged at *one and the same time*. I told him I had hitherto been led to understand that "charge" meant flow in a given direction, and "discharge" flow in the opposite direction, and therefore I presumed he somehow commutated his currents. "Not *exactly* that," he replied.

The chief points set forth as distinctive features of this battery are:—

1. "It produces a steadier and more constant and reliable light." Pity it is not *quite* steady; but this defect may be remedied in a future edition. Pity it is not quite constant; but since we are led to infer (Ye gods! who could doubt it?) that the E.M.F. is constant under varying loads, and knowing that the internal resistance is high, this battery is indeed truly and wonderfully made.

2. "The first cost of installation is far less than the cost of a dynamo and attendant steam or gas engine." A most desirable feature, and one which especially recommends itself

Digitized by Google

to contractors. For example, Mr. D'Humy is able to sell plant (*i.e.*, generating plant) sufficient for 25 10 candle-power lamps per £100. His charge, therefore, for 50 20 candle-power lamps would be about £350! Astonishment sways the quivering pen. Are not these figures quite sufficient to give a death blow to the engine and dynamo?

3. "The cost of maintenance is trifling by comparison." I have no doubt of it, for I have been favoured with some figures by one to whom Mr. D'Humy gave them direct, which give the remarkable result of $\frac{1}{16}$th of a penny per 20 candle-power lamp hour.

En passant I may mention that the output of each cell is arrived at in a charmingly simple fashion. Mr. D'Humy takes the current on short circuit and the E.M.F. on open circuit, multiplies these together, and arrives *at the output of each cell.* Happy thought. Send round Mr. D'Humy to all the dynamos in London to test their output in *the same way.*

4. "The battery is more convenient of storage." True, this battery is larger than any other existing battery, heavier, more bulky—in fact, it is "very fine and large," but, no matter; for

5. "No skilled and very little unskilled labour is required for its manipulation;" therefore it may be stowed away in half a dozen old barns, sheds, or pigsties.

7. "The batteries give off no noxious fumes;" for this reason the pigsty is the preferable place for them. Nitric acid never did give off noxious fumes. If the pigsty is leaky so much the better, for

8. "The chief liquid used is plain water," and so the "very little unskilled labour" may be absolutely dispensed with in wet weather.

9. "The economy of the battery is perfect." Hence we have $Z = 1$, a most admirable result, and one which, indeed, was to be expected, since the internal resistance is *high.*

"It is constant in its action, the storage of electricity never ceasing by day or night." This seems a little mystifying, but no doubt it is "claimed."

11. "The fluid flushed from the cells daily by the supply of fresh water is a slightly acidulated solution of iron, which is a high disinfectant, and most beneficial when discharged into the drains." Another reason for recommending the pigsty. (See remarks 5 and 7.)

The above are the chief points in the D'Humy battery, and at once show its enormous superiority over every other "system;" in fact, "it has at length solved the vexed question of house-to-house lighting by electricity." One cannot help picturing the besieged state in which Mr. D'Humy must have lived since the fame of his "invention" has been noised abroad. Go to No. 26, Gray's Inn-road, and see for yourself. Absolutely impossible! So engrossed is Mr. D'Humy in his "invention" that one has no chance whatever of seeing him, no matter at what hour of the day or night, or even if one waits all day it is impossible to get the desired audience.

In writing all this I am gnawed with pangs of jealousy when I think of the lucky contractor who supplies Mr. D'Humy with carbon plates, with iron, with acid, porous pots, and the like! 200,000 lamps in Madrid alone.

Mr. D'Humy, in comparing gas light with electric, compares what he considers the *actual* candle-power of a gas jet with the nominal candle-power of an electric lamp. This, no doubt, is simplicity, and after all that is the chief thing he isaiming at.

Possibly for the same reason, when comparing the output of his battery with that of the costly engine and dynamo, he takes the *nominal* horse-power of the engine and the product of the E.M.F. on open circuit and the current on short circuit, divided by 746 of the battery. And so one is obliged to agree with *Barker's Trade and Finance*, Aug. 10th, 1887, that "really there is no saying what wonderful achievements are yet to be developed through its (electricity) agency."

I propose to reserve my comments on the newspaper extracts for next week.—Yours, &c.,

ICONOCLAST.

P.S.—BATTERY *(log.)*:

The critics call me "Minehaha!"
"Mine" laughing "ha ha *Water.*"

RADIATION FROM LAMP FILAMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Mr. Robertson's interesting letter, I am afraid I have not made it quite clear in my articles that the question of roughness or smoothness does not come in as long as the outline of the heated body is the same ("Incandescent Lamp Manufacture XXI."). For instance, Mr. Robertson says:—"I think the points or hills on a dull surface carbon must cut off some of the light radiated from the hollows." I also pointed out that there would be no advantage in using a carbon with a high emissivity, as efficiency would still depend on temperature. So far I can corroborate Mr. Robertson's experiments as to alteration of hot resistance—that is to say, as far as my experience goes there is no apparent connection between hot and cold resistances of carbon.

I have tried very few experiments to determine the relative emissivity of grey and black carbons, and would be very glad if Mr. Robertson would test some of exactly the same surface—that is to say, the same outline in every direction—and see what candle-power they give at the same efficiency.—Yours, &c.,

JAS. SWINBURNE.

[CORRESPONDENCE *continued on page 397.*]

ELECTRIC TRANSMISSION OF POWER.

Now that the theatre at the Newcastle Exhibition has ceased to be used for dramatic entertainments arrangements have been made for the delivery of lectures every Monday and Saturday evening. The first lecture was delivered on Monday evening, by Prof. Garnett, the chairman of the Lectures Committee, the subject being "The Electric Transmission of Power." After brief reference to the methods commonly employed for transmitting power the lecturer referred to the growing importance of electric transmission for railways, tramways, and other purposes, giving various numerical particulars with which our readers are already familiar, and pointing out that although the power employed in electrical traction seemed large, yet the cost at Denver, where 10 horse-power per car is allowed, was only about one quarter of the cost of horse traction, and the cost is, after all, the important question. Some particulars were then given respecting the Messrs. Woodhouse and Rawson tramway in the Exhibition grounds, where the motor takes a load of between 12 and 13 tons up an incline of 1 in 30 and upon a very sharp curve. To take the car and bogey which carries the motor up this incline at the rate at which it travels requires about 24 horse-power on "the tow rope." After exhibiting a number of lecture room experiments illustrating the mutual action between currents and magnets, and the attraction of a solenoid for a turn-screw, &c., a half-horse Immisch motor was exhibited, and driven by the current ordinarily employed for lighting the footlights. The resistance coils which had been arranged for regulating the stage lights were of great service in reducing the E.M.F. (110 volts) in the theatre mains to suit the various motors exhibited. Prof. Garnett having pointed out the close analogies existing between the transmission of power by high-pressure water from an accumulator and the electrical transmission, called attention to the fact that when a steam engine or hydraulic engine is running most rapidly the consumption of steam or water is greatest, but in an electric motor the current diminishes with the speed. A 5 horse-power Immisch motor was then run in series with 28 Swan lamps, and it was seen that as the speed of the motor increased the light fell considerably, but rose almost to full brilliancy when a brake was applied so as to nearly stop the motor, and it was pointed out how the back E.M.F. produced by the motor regulated the current to the load. The analogy between motors and dynamos was then pointed out, and a transformer constructed by Messrs. Paris and Scott, of Norwich, for transformation from 400 volts to 100 volts, was exhibited in action and explained. These transformers have already been referred to in our columns. The machine in question is capable of running about 200 lamps. But the apparatus which evoked the greatest interest on the part of the audience was the set of machine tools lent to the exhibition by Mr. F. J. Rowan, of Glasgow. Two drills and a riveting machine were exhibited suspended from a frame in the front of the stage, and a $\frac{7}{8}$in. lead rivet was closed by the riveting machine, the lecturer, for obvious reasons, ceasing to lecture during the operation. There should be a great future for electro-magnetic machine tools in the shipyards of the Tyne. The half-horse Immisch motor exhibited is employed to drive a Blackman air propeller for the ventilation of the offices used by the cashier and the Finance Committee. The air is drawn through three rooms in succession, and it is needless to say that the ventilation is eminently satisfactory.

ELECTRICITY IN MINES.

Whether or not it is right that the House of Lords should "dare to dictate to the people's elected," it is certainly right that somebody should exercise a little common sense when legislation on the regulation of mines is in question; and in this relation the non-elected peers have rather the best of the comparison. It may be very desirable to substitute for the Davy and the Stephenson safety lamps some other and better appliance for the protection of workers in mines; but to prohibit the use of these lamps altogether, as the people's elected had done when they sent the Mines Regulation Bill to the Upper House, is something like prohibiting the use of gas in theatres altogether because gas is not the safest mode of lighting. The House of Lords removed this ban from the obnoxious lamps, seeing that the substitution of an absolutely safe lamp to take their place was not made obligatory in the Act, for the sufficient reason that no absolutely perfect lamp has yet been devised, or at all events has not yet been generally accepted. Although the electric lamp is, as we believe, the miners' lamp of the future, it may not in all cases be necessary; and in some cases it may be objected to on quite reasonable grounds. The electric lamp must be tried on its merits, and must fight its way as every other invention has had to do. And this is true also of the electric light for illuminating mines generally. If we wanted any fresh evidence of the good sense of the House of Lords in dealing with the Commons' suggestions it is furnished in the conduct of Mr. Fenwick, who opposed the Lords' amendments apparently because it was the Lords', and of Mr. C. Graham, who got himself suspended for "conscientiously" refusing to withdraw an offensive application of the phrase we have quoted in the opening sentence of this article. Reasonable people will mistrust any legislation whatsoever at the hands of fanatics who make their irrational prejudices a matter of "conscience."

Much as we desire to see an extension of the use of electricity in mines, its compulsory adoption would have given us no satisfaction at all. And this because all reforms of the kind here referred to must, to be really valuable, be adopted with a good grace and carried out with a sincere desire that they shall succeed. Reforms which have not the sympathy of the parties most affected by them are worse than useless, they are absolutely mischievous; for, being introduced unwillingly they are pretty sure to fail, and the result may retard their acceptance much longer than would be the case if they were left to win their way by merit rather than by legislation. It may be feared that some of the provisions of the Mines Regulation Bill which the Government succeeded in passing may fail because the House of Lords put a restraint upon their powers of "dictation;" and because the Bill as it stands is restrictive and vexatious somewhat beyond the limits of common sense and practical statemanship. A far more satisfactory guarantee on this point is the Home Secretary's positive assurance that the Government will do what it can to forward the welfare of miners by encouraging the use of electricity in their dangerous calling. This expression of approval is sufficiently valuable in itself, and, to our thinking, is as much as we can or ought to expect for the present. It may be a matter of conscience with some of our readers that none other than the electric light is desirable or safe in the explosive atmosphere of a mine; but none of them, we imagine, will consider it their duty to force their convictions on other people prematurely and by means of arbitrary legislation.

Some admirable safety lamps maintained by electricity have lately been devised; and we are able to state that electricity as a means of illuminating mines is steadily making progress. To these facts our columns are continually testifying; and we entertain no doubt that in due time a perfectly acceptable electric lamp will find its way into all the deep workings wherever a safety lamp is necessary. And further, that in the majority of mines electricity will rapidly supersede the use of bare lights of every other description. It rests with electrical engineers themselves and with electrical inventors to press their claims on the attention of the mine owners, and this they should do with all the energy at their command. The season of disaster is no doubt the most opportune for making converts, but, on the other hand, as we have just had occasion to point out in the case of the Exeter disaster, the season of security is the time to guard against an impending catastrophe; and, unhappily, where mines are in question the catastrophes are of ever-recurring frequency, so much so that they are treated too often as the unpreventable mishaps necessarily attendant on a dangerous avocation. According to the report just issued by the Chief Inspector of Mines there were 561,092 persons employed in the mines of Great Britain in the year 1886, and of these no fewer than 1,018 lost their lives by accidents of one kind or another connected with the workings. It is fair to assume that the greater portion of these casualties were due to either deficiency of light or the accumulation of explosive gases. It is our business, and the business of our readers, to patiently but steadfastly insist on the fact that these mishaps are not unpreventable, and that their occurrence is largely owing to the neglect of the one and only safeguard which human ingenuity has yet provided.

The importance of this subject was not overlooked at the recent meeting of the British Association, the members of

Digitized by Google

which made an excursion to the Astley and Tyldesley Salt and Coal Company's mine for the purpose of inspecting the electric light which had been lately installed in the workings. The mine in question is a comparatively new one, and does not belong to that dangerous class which most urgently call for the introduction of the electric light. But as a mere matter of convenience, the superiority of this form of illumination was demonstrated at Astley; and the impression left upon the minds of the visitors was that mine owners will not be long in discovering how greatly the efficiency of mining operations may be enhanced by the employment of electricity as the illuminant. As regards the gaseous and more dangerous class of mines, Mr. SWAN has made some recent improvement to his safety lamp, the particulars of which he described at the British Association meeting, and which will be duly given in our reports thereof. The device can be used both as a lamp and as a firedamp detector. In the latter capacity it will indicate the presence of this dangerous gas in proportions far below that for which all other known tests afford any evidence; and the operation is entirely free from the risk usually attending such tests by the appliances commonly in use. It has only recently been discovered that the presence of a very small percentage of firedamp in an atmosphere laden with coal dust will result in a mixture which is highly explosive. Hence it is that unlooked for explosions have often occurred in situations which had never been thought dangerous. With this knowledge before us the value of some highly sensitive indicator, such as that invented by Mr. SWAN, can hardly be over estimated; and we sincerely hope that it may prove in practice as convenient and as trustworthy as the ingenious inventor predicts it will be.

THE ELECTRICAL LIGHTING OF TRAINS ON THE GLASGOW UNDERGROUND RAILWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing a paragraph in your last week's issue relative to above, I have to state that two months ago some carriages did not have the contact pulley fixed at the proper height; but these have since been altered, and the lights now are quite as good, if not better, than at first. As I thought you might like to hear the result of six months' work, I beg to enclose note of same. The lamp-hours may not seem many, compared with the lamps in use and the time the trains have been running, but it should be remembered that the lamps are only lit, in the daytime, when the trains are in the tunnels.—Yours, &c., THOS. P. CARSWELL.

Bon-Accord, Douglas Gardens, Uddingston,
September 12, 1887.

Note of six months' working of electrically fitted trains up to 31st July, 1887:—

Number of carriages fitted	74
Number of lamps in use	307
Time lamps have been lit in "lamp-hours"	39,642
Number of lamps renewed	44*

* Eleven of the 44 lamps renewed were broken maliciously by passengers in the trains.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having quite recently inspected the system adopted of picking up the current for lighting the carriages, I can, with some authority, assure you that the report published in *The Electrician* of September 9th is quite ill-founded. Considering the difficulties attending the installation of the system, I think all impartial electrical men will agree that Mr. Carswell has initiated a new departure in railway lighting, which may be termed a "useful and economical compromise" between the old oil lamp and the complete electrical illumination by dynamo and storage batteries fitted to each train. The roller contact worked well, but in some carriages the spring pressure was not enough to cause good contact with the central rail, which is not to be wondered at. The carriages are fitted by the waggon department, who have no opportunity of testing the contact. This difficulty could be immediately removed by having a short line of rails and an electrician at the carriage works.—Yours, &c., KILLINGWORTH HEDGES.

Ballewan, Strathblane.

SELF-REGULATING DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Prof. Silvanus P. Thompson's book on "Dynamo-Electric Machinery" a number of mathematical formulæ are given expressing the conditions necessary for self-regulation in dynamos. I should feel obliged if any dynamo makers could find time to give information as to what extent these formulæ are in accordance with their practice in manufacture.—Yours, &c., M.

Calcutta, 19th August, 1887.

THE FORBES NON-POLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

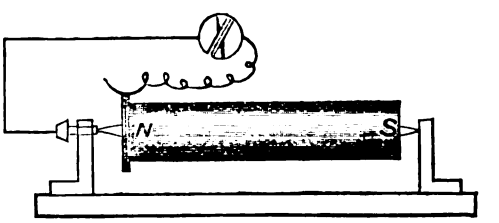
SIR: The typical Japanese is not inapt at drawing in his own particular style, but try to teach him the meaning of perspective, and though you make the facts as plain as pike staves you may waste years in the vain endeavour to make him understand it. To minds destitute of ingenuity what I have written in the course of this discussion cannot have been engaging, save in the way in which it appears to have interested Mr. Thompson, who has most fully misunderstood nearly every suggestion I have made.

Were I to attempt to correct the tissue of errors he makes in the letter published in to-day's *Electrician* the benefit would be very doubtful—good space wasted undoubtedly. He may therefore enjoy the fruits of his ideas, whatever they are, in peace, so far as I am concerned.—Yours, &c.,

Staveley, September 2nd, 1887. R. SNOWDON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To help bear me out I will now quote the immortal Faraday, whose experimental accuracy no one will dispute. In Vol. I., page 63, he says:—"I endeavoured to ascertain whether it was essential or not that the moving part of the wire should, in cutting the magnetic curves, pass into positions of greater or lesser magnetic force." And to prove the point "a copper disc was *cemented* upon the end of a cylinder magnet with paper intervening, *the magnet and disc were rotated together*, and collectors brought in contact with the circumference and the central part of the copper plate. The galvanometer needle moved, and the direction of motion was the same as that which would have resulted *if the copper only had revolved and the magnet been fixed.*" The italics are mine. There is no drawing,



Faraday's Experiment.

so I send you what I think is a fair representation of the experiment. Let us see what bearing it has on our present discussion. Firstly, the disc was cemented to the end of the magnet and rotated with it. If Mr. Thompson is of the same opinion still, he will say the current is the result of the rotating lines of force cutting the stationary conductor leading from the periphery of the disc. Be it so. But, secondly, the magnet was fixed and the disc only allowed to rotate. The fixed conductor must necessarily have been neutral in this case. If we now follow out Mr. Thompson's idea, that the lines are inseparably connected

Digitized by Google

with the magnet and rotate with it, we are driven to these conclusions:—In Faraday's first experiment the wire could only be the generating conductor and the rotating disc so much superfluous metal, because a rotating disc could not cut lines of force rotating in the same direction and at the same speed. On the other hand, in the second arrangement—the magnet at rest and the disc revolving—the disc only could be the generator and the wire simply a neutral conductor. I cannot believe Nature to be so whimsical and erratic in her workings as this, and for reasons before stated I have no doubt whatever that in both of the above experiments the disc was the only generating conductor in the system.

Mr. Thompson again asks what the pivot arrangement proves. But he expects too much. I have endeavoured to prove that my theory is right rather than to show that Mr. Thompson is wrong; but in the latter case I must refer him to my previous letters to save repetition.

In his remarks on my proposed double-magnet experiment, published August 19th, Mr. Thompson fixes on an accidental feature of the system by attributing the current production to the wire bridge that electrically connects the two magnets; and in reproducing that diagram in his own letter he implies that the bridge would fully account for the current. True, there would be current from this cause, but it would be comparatively weak and opposed in direction to what I may term the legitimate current—that which is caused by the iron molecules of the extreme poles intersecting the lines of force. The output of the machine would be as the difference between these two opposed currents. However, a thin piece of brass could be arranged, in place of the wire and mercury cups, so as to hug and impinge on the two magnets respectively; and, better still, a solenoid could be used instead of a permanent magnet. The core would be divided at its equator, and, being of soft iron, the lines of force would be confined to it throughout its length, and the thin brush of brass would then undoubtedly be parallel to the external lines. Mr. Thompson asks me to explain how two discs mounted on the same axis can be made to develop current; and I must again refer him to my first letter, July 8th. In that a diagram of a machine is shown in which any number of discs are fixed to a common axis rotating in magnetically-closed solenoids. The only difference in its principle to the experimental apparatus that we have discussed is that the latter are so arranged as to make their external polarity evident by having lines of force exterior to themselves, and these lines as they lead from one pole to the other are cut by the rotating surface of the magnets—in fact, they are permanent magnets. But in my machine two or any even number of solenoids are placed parallel to each other—say, two—and the N of one is adjacent to S of the other. These two poles of opposite sign abut against an iron frame which magnetically closes the two poles, and at the same time supplies the bearings for the two shafts. By this means the lines are confined to the cores, and externally the machine would not develop any polarity other than that resulting from imperfect workmanship, or what may be termed practical or accidental defects.

Mr. Thompson notes that if a magnetised bar be moved bodily from one portion to another, it and its magnetic lines are inseparably connected and move together; and he asks why they should not be equally inseparable, and have an equal tendency to move together, when the same bar is moved by being rotated on its axis. Now, to consider this point it seems to me that we must first start from an incontrovertible fact. This. Iron has a greater affinity or a greater concentrative power for magnetism than any known substance, certainly more than the air space surrounding a bar magnet. I am impressed with the idea that so long as magnetism is confined to space or matter that is magnetically homogeneous it is too ethereal or too immaterial to be displaced. The space traversed by the movement of a magnetised bar from one point to another in air is not homogeneous because the magnet itself occupies part of that space. Therefore to expect the lines of force under such conditions to be stationary while the bar itself moved would be to expect magnetism to have the same affinity for air as for iron, inasmuch as to maintain its position the magnetism would have to leave the iron to take its place in air. It is this concentrative power or magnetic fixity of iron that prevents the separation. If the same magnetised bar is rotated on its axis the case is different. Its molecular construction being homogeneous, there is no tendency for the lines of force to be left in less magnetic space, because as one molecule, in rotating, advances, another of equal magnetic capacity is ready to take its place. A line of force, to speak honestly, is no respecter of molecules, so long as they are all alike.—Yours, &c.,

E. L. VOICE.

September 5th, 1887.

[It appears to us that the further discussion of this subject is unnecessary, both sides being most emphatic in "agreeing to differ."—ED. *E.*]

LITERATURE.

Electrical Distribution by Alternating Currents and Transformers. By RANKIN KENNEDY. (London: H. Alabaster, Gatehouse and Co.)

This is a little book of 60 pages, containing a reprint (with some additions) of a series of papers which originally appeared in our contemporary, the *Electrical Review*.

The subject of the distribution of electricity by alternating currents presents an alluring field for the display of mathematics, and hitherto its somewhat meagre literature has been generally more or less over the head of the average reader. This is a fault which cannot be charged against Mr. Kennedy. He tells us in the preface that "this pamphlet is issued simply as a collection of useful and interesting information gathered together during the past four or five years from experiments, practical applications, and specifications." The modest claims of the author are fully borne out by the contents of the book, as will be seen by the brief synopsis which we shall proceed to give.

Chapter I. deals briefly with the alternate current dynamo. The author mercifully refrains from inflicting upon us a disquisition upon the many obsolete types which are perfectly familiar to electricians, and is contented with cataloguing their titles. On the other hand, we are pleased to find a description of his own machine, which is not at present so widely known. In Mr. Kennedy's alternating current dynamo the armature consists of a cast-steel wheel, on the periphery of which insulated iron tape is wound to a depth of 8in. (in an armature of 4ft. diameter); slots are then planed out on both sides to contain the coils, which are wound up flush with the face of the armature. The field-magnets are of the Siemens type, with projecting poles on either side equal in number to the armature coils. Regulation for constant E.M.F. is effected by hand, but it is stated that for the larger sizes the resistance and self-induction of the armature are so low that no adjustment of the exciting current is required except in the neighbourhood of maximum output. On this question of self-induction Mr. Kennedy, at page 8, makes a slight slip, which should be corrected in a subsequent edition. He says "the magnetising effect of the current in the armature coils is proportional to the number of turns in the coils, and the amount of self-induction is proportional to the same thing." Self-induction is, however, proportionate to the *square* of the number of turns. For constant current regulation Mr. Kennedy adopts a plan which is analogous, or rather complementary, to that employed in the Zipernowski-Déri system for obtaining constant difference of potential. He connects the primary coil of a transformer as a shunt across the terminal of the machine, commutates the secondary current on the shaft of the dynamo, and employs this current to excite the field in conjunction with a separate constant-current exciter. We should be glad to be assured that this method gives a sufficiently good regulation in practice, because we understand that in the Zipernowski-Déri system it has been found necessary to supplement the converse arrangement by hand regulation.

Chapter II. deals with transformers, and contains a number of illustrations, with adequate descriptions of the several forms which had been devised up to the spring of the present year. As Mr. Kennedy justly observes, the transformer is one of the

Digitized by Google

simplest pieces of electro-magnetic apparatus imaginable. Given a closed magnetic circuit with two separately insulated conductors wound thereon, the only constructive problem is to find the form which is cheapest to make and easiest to repair, combining the shortest magnetic circuit with the most ample ventilation. This last point is one on which Mr. Kennedy fails to lay so much stress as is desirable. The output of any given transformer is limited solely and simply by the rise of temperature in the coils and in the iron, hence ample ventilation is of the highest degree of importance. In certain transformers of recent design which we have had an opportunity of inspecting this fact has been fully recognised and has received most careful attention. Mr. Kennedy traces the history of the apparatus from the original solid iron ring of Faraday, and the open circuit induction coil of Rhumkorff, down to the modern types of Ferranti, Zipernowski Déri and Kennedy; giving due honour, of course, to Messrs. Gaulard and Gibbs, who, although somewhat unfortunate in the type of apparatus actually chosen, yet deserve the positive gratitude of the electrical world for so persistently forcing the claims of the system upon its (at first somewhat reluctant) attention. For small sizes Messrs. Dick and Kennedy make a transformer consisting of a Pacinotti ring with coils wound between the projecting teeth, the whole being then overwound (around the periphery) with iron tape. For larger sizes they prefer what Mr. Kennedy calls the "subdivided" type. This consists of a number of small transformers with rectangular iron cores stamped out of band iron, and so built up as to form one large cubical structure in which the several magnetic circuits are all closed. The advantage claimed for this form is that if any one pair of coils breaks down it can be immediately cut out of circuit without interfering with the remainder. On the other hand, as each primary coil has to have as many ampere-turns as if it did the whole of the work, it would appear that the construction entails some loss of economy.

The Ferranti transformer consists of two bundles of hoop iron, which are laid side by side through the same pair of coils, the ends being then doubled back outside so as to close the magnetic circuit. There is some tendency to heat in this form, but, as our readers are aware, it has met with great practical success at the Grosvenor Gallery installation.

Pages 24-27 deal with "the practical rules for the construction of transformers." Mr. Kennedy is, perhaps, scarcely so happy in his treatment of this part of the subject. His scheme does not include the mathematical investigation of any part of the problem—which, indeed, as yet has only been adequately treated by Kapp in his very beautiful graphical method. This being the case the author would perhaps have done better to have confined himself to pointing out the line of experiment which should be undertaken for the empirical determination of the proper windings. This is really all that his discussion amounts to, though by means of two so-called "laws" leading to certain "rules" a rather delusive appearance of precise theoretical treatment is imparted to the pages.

The first of Mr. Kennedy's "laws" runs as follows:—

"When no work is being done in the secondary circuit there should be no current in the primary circuit—that is, the counter pressure in the primary must be equal to the primary pressure or very nearly equal thereto."

This merely amounts to saying that the impedance of the primary coil *per se* should be sufficiently high to avoid waste of energy with open secondary circuit—which is, of course, quite true, although the statement seems scarcely entitled to the dignity of being termed a law.

The second law, which is similar in form, admits of being translated into the assertion that the core should preferably be worked upon the straight part of the saturation curve, which is also true. Then come Rules I. and II., amounting to this, that if we know already the counter E.M.F. generated per foot of wire in the primary, at a given number of alternations per second, having given also the desired number of volts at the terminals of the primary and secondary coils, then we can find the number of feet of wire in each coil by dividing in each case the total number of volts by the number of volts induced per foot of wire. This is again perfectly incontestable, only it must be confessed that the "if" is "rather a large order." Mr. Kennedy evidently perceives as much, for he recommends that a trial should be made upon the assumption of an induction of two volts per foot, which in his experience has generally been found to be an outside figure; wire can then be added to the primary until the impedance with open secondary circuit has reduced the current to an economical value; from this the turns on the secondary are found by the simple ratio of the volts. This is, no doubt, a good practical way of determining the windings, when once the vital question of the dimensions of the core has been settled. But upon the latter point Mr. Kennedy is content with the somewhat naïve remark that "data for calculating the size of the core may be obtained from dynamo builders," and he offers no remark on the bearing of this matter upon the "two volts per foot." It inevitably strikes one also that if Mr. Kennedy's instructions be too implicitly followed a core might easily be selected upon which we should afterwards find either a lack of room, or a waste of space in the aperture left for the coils, so that the method is really a purely experimental one.

Mr. Kapp's ingenious device of superposing the saturation curve of the iron upon the right line representing resultant magnetisation in his graphic construction (see *Industries*, April 15th, 1887) has already been placed before our readers (though not referred to by Mr. Kennedy), and it will interest them to know that a transformer designed by the aid of this method has been found in practice to conform with the predicted results to a remarkable degree of accuracy.

Chapter III. contains a detailed enumeration of the various patents which have been taken out dealing with systems of distribution in which transformers are employed. The earliest of these is that of M. Jablochkoff, in 1877, who proposed to make use of induction coils with vibrating interruptors for feeding his candles with a higher E.M.F. than that in the mains. We believe that the present owners of this patent contend that the claims cover the whole ground of the use of transformers for distribution, and entitle them to the exclusive use of the method. In November, 1878, a provisional specification (No. 4611) was filed by Messrs. E. Edwards and A. Normandy in which the use of alternating currents with induction coils was for the first time described. This patent was not proceeded with, but the appearance of the provisional specification having constituted publication, it is difficult to see how any "master-patent" of still later date can be established. The Gaulard-Gibbs specification is dated 1882, and follows closely on the lines of the 1878 specification above referred to.

In the following year (1883) Mr. Kennedy pointed out the advantages of the parallel system of connection as giving nearly perfect automatic self-regulation. Mr. Kennedy takes a pardonable pride in recalling this circumstance, and to his credit stands the fact that at the present time the whole of the successful installations of transformers in operation are working upon parallel mains. Nevertheless, we venture to think that it is somewhat rash to assert that the series connection is a total impossibility. In connection with the experiments of Mr. Kennedy in the year 1883 it should be observed that they were carried out with series-wound transformers (or, as Mr. Kennedy strenuously objects to this abbreviation, let us say wound-for-series-connection transformers). This circumstance led him at the time to overlook the possibility of using high tension in the mains with a parallel system, so that the letter in which he describes the self-regulation attainable by this means ends with these words: "But what about the size of the conductors in such a system? Prodigious!" This unfortunate remark does not appear to have been recalled by Mr. Kennedy until fully three years later, and in the meantime MM. Zipernowski-Déri and Blathy were enabled to claim the employment of the parallel system in a practical shape as an independent discovery of their own. The controversy between these gentlemen does not, however, appear to us to be one of any great importance either commercially or otherwise.

Mr. Kennedy's final development of his own particular distributing system involves the employment of a low potential dynamo, together with a pair of transformers of large size which raise the potential from 50 to 2,000 volts. The

Digitized by Google

two secondary coils are then connected to a three-wire network of mains by which the current is distributed to the local transformers. In the diagram on page 43 the arrows showing the direction of the current in the external wires should on one half of the circuit have been turned the other way. It is evident that the main transformers must be so connected that they tend to send simultaneous currents in opposite directions through the middle wire.

Chapter IV. deals with measuring instruments for alternating currents. Dr. Fleming's disc galvanometer (first described in this journal, May 6th, 1887) is illustrated, together with Sir William Thomson's electrostatic voltmeter.

The last chapter, under the title of "Accessories," contains a recapitulation of the interesting experiments of Prof. Elihu Thomson on the repulsion exhibited by a closed circuit having a large time constant in an alternating field. Incidentally it is stated that there is no theoretical reason why alternating current motors should not be as good as continuous current motors—a conclusion which we fear is not as valid as could be wished. A synchronously running motor has certain very weak points, and the outlook for non-synchronous motors is, in view of the arguments set forth by Mr. Kapp (*see* paper in our present issue) somewhat blank.

Before concluding this notice it may be well to refer for a moment to the incorrect use of Oliver Heaviside's term "impedance," which occurs on page 6. It is there spoken of as synonymous with "counter-electromotive force." This is by no means the case. The impedance of a conductor is expressed by the formula

$$\sqrt{R^2 + (2\pi n L)^2},$$

where n is the number of alternations per second, and L the coefficient of self-induction. The impedance of a conductor without self-induction is therefore numerically equal to its resistance, and it would be proper to speak of the impedance of a 100-volt incandescent lamp as equivalent, say, to 160 ohms. The counter electromotive force, upon the other hand, generated by a sinusoidal alternating current of value I is measured by

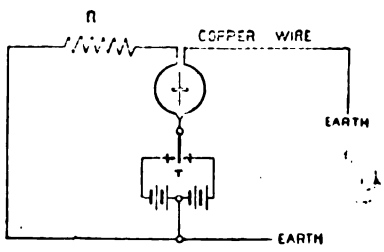
$$2\pi n L I.$$

In conclusion, we may be permitted to congratulate Mr. Kennedy on having produced the first connected account of a subject of such great and increasing importance.

ON THE COEFFICIENT OF SELF-INDUCTION IN TELEGRAPH WIRES.*

BY WILLIAM HENRY PREECE, F.R.S.

A considerable amount of attention has been devoted during the past two years to self-induction in apparatus, and various methods have been proposed and instruments devised to measure the coefficient L. These methods are of very little consequence to telegraphy, for electro-magnetic inertia (a much better term than self-induction for the general phenomena) has been entirely eliminated from high-speed telegraphic apparatus. It remains, however, an important factor in iron wires when they are used for high-speed telegraphy and for telephony.



In a paper read before the Royal Society on March 3rd of this year on the limiting distance of speech by telephone, I excluded electro-magnetic inertia as a factor in considering the time constant of copper wires, but as my measurements were not then complete I was unable to embody them in that paper, or to give the reason for not doing so.

The coefficient (L), which is a length, and throughout this paper indicates the number of units of 10^9 centimetres involved per mile, is very simply determined on circuits fitted up with Wheatstone apparatus on the duplex system, for the compensating coils (R) are double wound so as to be entirely free from any self-induction, while the line wire itself, if subject to it, will vary its effective resistance according to the well-known law dependent on the frequency of the periodic currents. When a Wheatstone transmitter (T) works at the rate of 50 words per minute, its frequency (p) is 20 per second, and when working at 250 words per minute its frequency is 100, so that at that speed $2\pi p$ or $m = 628$, and, therefore, $m^2 = 400{,}000$ approximately.

Now, since r the actual resistance per mile to steady currents becomes when these currents are periodic $(r^2 + L^2 m^2)^{\frac{1}{2}}$—sometimes called the throttling or spurious resistance—it will follow that L^2 must equal ·000025 to increase r by unity. But with copper wire of 270 miles long, delicately and sensitively balanced by steady currents, it has been impossible to observe any change whatever in the value of R when $m = 628$, and therefore L^2 must be less than $\frac{1}{2}\frac{1}{5}\frac{1}{0}$ of this amount, or less than ·00000001. L is therefore so small for copper that it may be neglected.

It must be remembered that the currents employed in high-speed telegraphy differ but very little in frequency from those of the dominant notes employed in telephony. We have worked from London to Bristol at the rate of 600 words per minute. This means a pitch of 240, which would give a value to m of 1,507. No difference whatever can be perceived, even at this high speed, in the character of the currents employed to distinguish them from those used for the transmission of slow signals through cables, or from those required for telephony.

I have spoken with telephones over 270×2, or 540, miles of copper wire with a clearness of articulation that is entirely opposed to the idea of the presence of any measureable magnitude of L.

It is, however, quite another matter with iron.

I have adopted several methods of measuring L in iron wire.

1. The duplex method.
2. The direct measurement of the time constant.
3. The limiting distance of speech.

1. The duplex method is the same as that used for copper wires.

$$R' = \sqrt{(R + L^2 m^2)}.$$

R is the actual total resistance to a steady current.

R′ is the observed total resistance due to frequency $\frac{m}{2\pi}$.

Two circuits of different resistances were taken, the one a metallic loop, 230 miles long, through Birmingham; the other a wire to Anglesey, 250 miles, using earth as return, each wire being of iron.

(*a*) . . . . . R = 3480ω.
R′ = 3560ω.
$m = 2\pi \times 100$.
L came out = ·00517.

(*b*) . . . . . R = 3000.
R′ = 3050.
$m = 2\pi \times 80$.
L came out = ·0048.

The mean of these two observations is ·00498.

2. The direct measurement of the time constant $\left(\frac{L}{R}\right)$ was taken with a chronograph similar to that described in my paper [*Proc.* Royal Society, March 3, 1887] on two wires erected on the same poles between Barnet and Newcastle, a distance of 261 miles, the one, No. 14 copper, and the other, No. 7½ iron.

The copper wire circuit—

Resistance = 2645ω.
Capacity = 7·44 microfarads.
Insulation = 47·6 megohms.

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

The iron wire circuit—

Resistance = 3433ω
Capacity = 8·13 microfarads
Insulation = 36·4 megohms.

The time constant was for—

Copper ·0044 second.
Iron ·00667 second.

If we neglect self-induction, then, the time constant being KR, or the product of the total capacity and the total resistance, we have KR for

Copper circuit = 19678
Iron circuit = 27910

and $$\frac{27910 \times \cdot0044}{19678} = \cdot00624'',$$

which should have been the time constant of the iron circuit if there had been no self-induction; but the time constant was ·00667, and the difference, ·00043, was that due to self-induction in the iron wire.

The actual length of iron wire is 255 miles, and its resistance 3068; hence

$$L = \cdot0051.$$

3. The limiting distance of speech test is given in my paper read at the Royal Society. I there pointed out that the distance to which we can speak varies in the ratio

$$\frac{\text{Iron}}{\text{Copper}} = \frac{10000}{12000},$$

and that this difference is due to the presence of electromagnetic inertia in the iron.

Now, if we assume that in the formula

$$x^2 = A/K\,r$$

r becomes $\sqrt{(r^2 + L^2m^2)}$.

Then it will be necessary for r, which is ordinarily 12ω per mile, to become 19ω to account for such a change, and the following table shows the different values of m and L, which will give this result:—

TABLE.

Values of $\sqrt{r^2 + L^2 m^2}$ for No. 7½ iron wire.

Values of m.	Values of L.					
	·0015	·002	·003	·004	·005	·0100
0	12,000	12,000	12,000	12,000	12,000	12,000
100	12,001	12,002	12,004	12,007	12,010	12,042
250	12,006	12,010	12,023	12,042	12,065	12,258
500	12,023	12,042	12,093	12,165	12,258	13,000
1,000	12,093	12,165	12,369	12,649	13,000	15,620
1,500	12,209	12,369	12,816	13,416	14,151	19,209
2,000	12,369	12,649	13,416	14,422	15,620	23,324
3,000	12,816	13,416	15,000	16,971	19,209	32,311
3,600	13,159	13,994	16 144	18,745	21,633	37,947
5,000	14,151	15,620	19,209	23,324	27,731	51,420
9,420	18,538	22,337	30,702	39,545	48,604	94,961

If we take L as ·005 it will follow that the value of m is 3,000, and therefore the dominant pitch in speech when transmitted by a telephone would be 480, but this point requires further inquiry, and I am now engaged in investigating it.

The value of L for iron wire is therefore by the

Duplex method ..... ·00498
Direct measurement ..... ·0051
Mean result ..... ·00504

I have assumed the value of L in copper to be 0; but let us, on the other hand, consider that it has some appreciable value. This value would reduce the ascertained value of L in iron when the two are directly compared. But the concordance of the results justifies the conclusion that the value of L in iron is ·005, and therefore inversely it justifies the assumption that L in copper approximately = 0; for if it did not, then we should see a difference when comparing copper and iron less than that observed by the direct measurement of iron alone.

Since we are dealing with circuits precisely similar in geometric form, the value of L will approximately be—

$$\frac{\text{Copper}}{\text{Iron}} = \frac{1}{\mu};$$

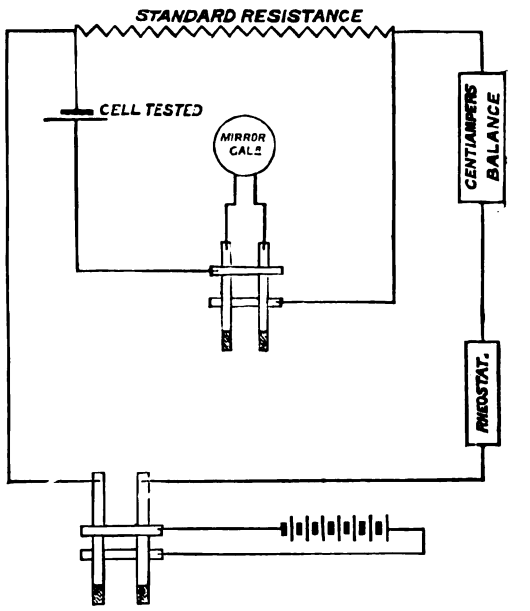
μ is usually taken for iron wire as equal to 300. If that be so, then L for copper, assuming that for iron to be ·00504, should be ·0000168, which is small enough to be neglected. But Prof. Ewing, F.R.S.,* has shown that for very soft iron wire strongly vibrated μ may be taken as high as 20,000, and that values of 1,000 and upwards are quite likely to be found in practice. If we take μ as 1,000 L for copper would be ·000005.

The virtual absence of electro-magnetic inertia in copper is leading to its extensive adoption for telegraphy, and no other wire should ever be used for telephony.

ON THE APPLICATION OF THE CENTI-AMPERE OR THE DECI-AMPERE BALANCE FOR THE MEASUREMENTS OF THE E.M.F. OF A SINGLE CELL †

BY SIR WILLIAM THOMSON, F.R.S.

For the purpose of measuring the E.M.F. of a single cell the centi-ampere or the deci-ampere balance is put in circuit with a battery of a different number of cells, a rheostat, and a standard resistance, in the manner shown in the diagram. The current measured by the balance is then varied by means of the rheostat until the difference of potential between the ends of the standard resistance is exactly equal to the potential of the cell. This equality is tested by placing the cell in series with a mirror galvanometer or a quadrant electrometer in a derived circuit, the ends of which are connected with the ends of the standard resistance, and observing whether any deflection is obtained by closing this circuit.



Suppose, for example, the standard resistance to be 10 ohms, and the current as indicated by the balance 0·108 ampere when no deflection is obtained on the mirror galvanometer by closing its circuit, the potential of the cell is 10 × ·108 or 1·08 volt. Proper precautions must of course be taken to eliminate thermo-electric or other disturbances in the circuit.

The quadrant electrometer may be used with advantage in

* *Phil. Trans.*, Part II., 1885, p. 568.

† Paper read before the British Association Meeting at Manchester, September, 1887.

the derived circuit when it is important that no current should flow through the cell, but the mirror galvanometer has the advantage of much greater sensibility.

NEW ELECTRIC BALANCES.*

BY SIR WILLIAM THOMSON, F.R.S.

These balances are founded on the mutual forces, discovered by Ampère, between the fixed and movable portions of an electric circuit. The mutually influencing portions are usually circular rings. Circular coils or rings are fixed with their planes horizontal, to the ends of the beam of a balance, and are each acted on by two horizontal fixed rings placed one above and the other below the movable ring. Six grades of instruments are made, named centi-ampere, deci-ampere, ampere, deca-ampere, hecto-ampere, and kilo-ampere balance. The range of each balance is about 25. Thus, the centi-ampere balance will measure currents of from 2 to 50 centi-amperes, while the kilo-ampere balance will measure currents of from 100 to 2,500 amperes. Since the indications of the instrument depend on the mutual forces between two parts of an electric circuit of permanent form and relative position, they are not subject to the changes with time which are so troublesome in instruments the constants of which depend on the strength of permanent magnets.

The most important novelty in these balances is the connection between the movable and the fixed parts of the circuit. The beam of the balance is suspended by two flat ligaments made up of fine copper wires placed side by side. These ligaments serve instead of knife edges for the balance, and at the same time allow the current to pass into and out from the movable coils. The number of wires in each ligament varies from 20 in the centi-ampere to 900 in the kilo-ampere balance. The diameter of the wire is about one-tenth of a millimetre, and each centimetre breadth of the ligament contains about 100 wires.

The electric forces produced by the current are balanced by means of weights, which can be moved along a graduated scale by means of a self-relieving pendant. Two scales are provided, one a scale of equal divisions, the other a scale the numbers on which are double the square roots of the numbers on the scale of equal divisions. The square root scale allows the current to be read off directly to a sufficient degree of accuracy for most purposes. When high accuracy is required, the fine scale of equal divisions may be used, and the exact value of the current obtained from a table of doubled square roots supplied with the instrument.

An engine room voltmeter on a similar plan was described. It consists of a coil fixed to the end of a balance arm, suspended as above described, and acted on by one fixed coil placed below it. The distance apart of the two coils is indicated by means of a magnifying lever, and serves to indicate the difference of potential between the leads to which the instrument is connected. The coils of the instrument are of copper wire, and an external platinoid resistance of considerably greater amount is joined in circuit with it. The electrical forces are balanced by means of a weight placed in a trough fixed to the front of the movable coil, and weights suited to the temperatures 15deg., 20deg., 25deg., and 30deg. C., as indicated by a thermometer with its bulb in the centre of the coils, are provided.

Two other instruments were described, namely, a marine voltmeter suitable for measuring the potential of an electric circuit on board ship at sea, and a magneto-static current-meter suitable for a lamp counter.

In the marine voltmeter an oblate spheroid of soft iron is suspended in the centre of, and with its equatorial plane inclined at about 40deg. to, the axis of a small coil of fine wire by means of a stretched platinoid wire. When a current is passed through the coil the oblate of soft iron tends to set its equatorial plane parallel to the axis of the coil, and this tendency is resisted by the rigidity of the suspension wire.

The lamp counter is a tangent galvanometer with special provision for preventing damage to its silk fibre suspension, and for allowing the constant to be readily varied by the user to suit the lamps in his circuit.

* Paper read before the British Association Meeting at Manchester, September, 1887.

ON THE MAGNETISATION OF HADFIELD'S MANGANESE STEEL IN STRONG FIELDS.*

By Prof. J. A. EWING, F.R.S. (University College, Dundee), and Mr. WILLIAM LOW.

Messrs. Hadfield, of Sheffield, manufacture a steel containing about 12 per cent. of manganese and 0·8 per cent. of carbon, which possesses many remarkable qualities. Prominent amongst these, as the experiments of Hopkinson, Bottomley, and Barrett have shown, is a singular absence of magnetic susceptibility. Hopkinson, by applying a magnetic force, $\mathfrak{H}$, of 244 C.-G.-S. units to a specimen of this metal, produced a magnetic induction, $\mathfrak{B}$, of only 310 C.-G.-S. units; in other words, the permeability μ was 1·27 and the intensity of magnetisation $\mathfrak{I}$ was a little over five units. We are indebted to him for the suggestion that it would be interesting to apply to this metal the "isthmus" method of magnetisation (the results of which, as applied to wrought iron and cast iron, have been described in a former paper), with the view of seeing whether the magnetic resistance of manganese steel could be broken down by applying a very strong magnetising force.

Messrs. Hadfield were kind enough to supply a sample of the metal for experiment, out of which a bobbin was turned, with some difficulty, of a form resembling those used in testing wrought iron and cast iron, but with a wider central neck. The bobbin was magnetised by placing it between the pole-pieces of Prof. Tait's large magnet; and the induction within the neck, and also the field in the air immediately surrounding the neck, were measured in the usual way, by the help of two induction coils and by drawing the bobbin suddenly out from between the magnet poles. A large number of readings were taken, while the field magnet was excited with currents ranging from about 1 to 40 amperes. These gave values of the magnetic field (in the air immediately surrounding the central neck of the steel bobbin) ranging up to 5,200 C.-G.-S. units, and values of the induction $\mathfrak{B}$ within the neck ranging up to 7,700 C.-G.-S. units. To be more exact, these latter were the values of that part of the induction which disappeared when the metal was drawn out of the field, but the correction for residual magnetism was probably negligible. The ratio of induction to field had a nearly constant value when the field ranged from about 1,000 C.-G.-S. to 5,200 C.-G.-S.; the values of this ratio, calculated from the observations, fluctuate somewhat, but do not appear to undergo any progressive change. The mean value of $\frac{\mathfrak{B}}{\text{outside field}}$ is 1·45, a quantity which we may probably take without substantial error as the value of the permeability μ.

To test the influence of still stronger magnetic fields, a second series of experiments was made with a composite bobbin made up of a cylindrical shank, extending from end to end, of manganese steel, and conical pole-pieces of soft wrought iron forced on to the steel shank so as to leave only a short length of it (about 3 millimeters) bare in the middle. With a given current in the field magnets, this gave much higher values of the field and the induction in the central neck, because the wrought iron cones now substituted for the conical ends of the solid steel bobbin that had been formerly used gave an easier path for the lines of induction to converge to the central neck. The field now ranged up to values slightly exceeding 10,000 C.-G.-S. units, and the highest induction reached was about 15,000 C.-G.-S. units. In this series of experiments, as in the former series, the ratio of induction to field fluctuated irregularly; but its mean value was nearly identical with the former mean, namely 1·46. The intensity of magnetisation $\mathfrak{I}$ was forced up to values lying between 300 and 400 C.-G.-S.

The experiments make it clear that even under magnetic

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

forces extending to 10,000 C.-G.-S. units the resistance which this manganese steel offers to being magnetised suffers no break-down in any way comparable to that which occurs in wrought iron, cast iron, or ordinary steel at a very early stage in the magnetising process. On the contrary, the permeability is approximately constant under large and small forces.

The conclusion has some practical interest. It has been suggested that this steel should be used for the bed-plates of dynamos and in other situations where a metal is wanted that will not divert the lines of induction from neighbouring spaces. In such cases the magnetic forces to which manganese steel would be subjected would certainly lie below the limit to which the force has been raised in these experiments. We may therefore conclude that in these uses of the material, it may be counted upon to exhibit a magnetic permeability only fractionally greater than that of copper, or brass, or air.

CLARKE'S TELEMETER SYSTEM.*

BY F. R. UPTON.

The problem of moving a secondary hand in synchronism with a primary hand by means of electricity has been long before electricians. Mr. Chas. L. Clarke, of New York, has given to the world one solution of this problem in the instruments which have been named the transmitter and receiver of the Telemeter System.

The need of a reliable electrical thermometer is very marked in the artificial refrigerating systems which are now so much used in the United States. From this necessity came this invention. Mr. Robert Hewitt, of New York, who was at the time engaged in the refrigerating business, after trying to make an electrical thermometer, and meeting with only partial success, applied to Clarke to aid him. The result I have the honour to bring before you in the instruments which are described as follows :—

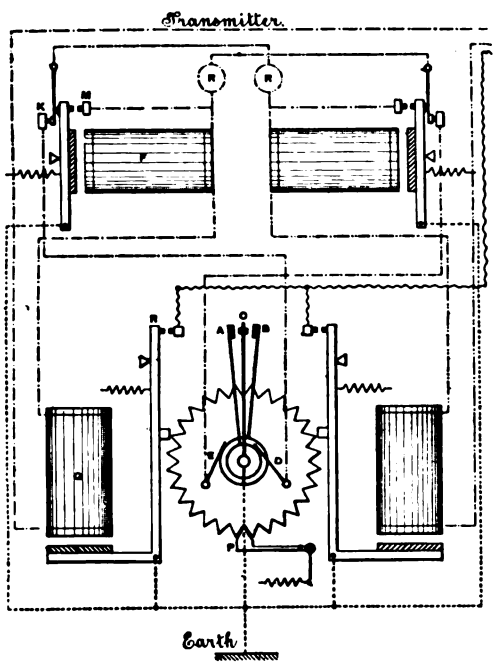

FIG. 1.

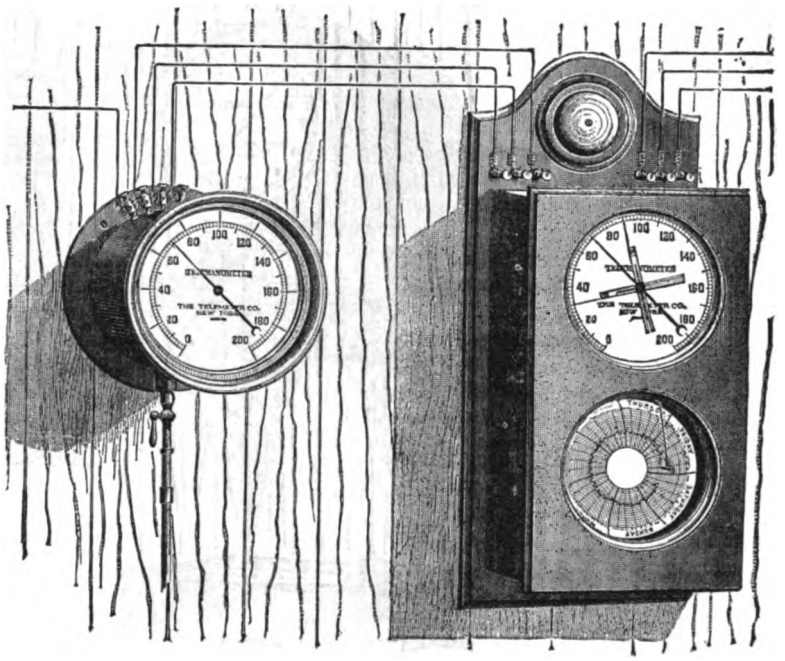
In the transmitter or primary instrument the toothed wheel and the contact arms A and B (Fig. 1) are supported by and revolve upon the same shaft. In line with this shaft is another shaft carrying the contact arm C. This shaft and contact arm are actuated, either by the spiral bi-metallic thermometer, the Bourdon tube of a steam gauge, or the pulley of a water gauge, as the case may be. Each of the contact arms A B is supported on a grooved hub insulated from the shaft, and electric contact is made by springs D E resting in the grooves of the insulated hubs. The dotted circuits in the transmitter represent the connections to the metallic frame of the instrument and to the return circuit or ground. In the receiver they represent the connections to the metallic frame and to the battery.

Assuming that the initial instrument is a thermometer, and that the temperature is rising, the thermometer, as the spiral opens, will move the contact arm C towards B until contact is made. The circuit will then be closed through the resistance spool R, magnets F G H. F is so adjusted and proportioned as to be the first in the series to work. As the armature of F is attracted it releases the flat spring K, which opens the circuit of the opposite side of the system. Contact is next made at M. This contact is a shunt of no resistance around the primary contact B C and the resistance R, substituting a firm contact in place of the delicate primary contact. After F the magnets G H operate, either simultaneously or one after the other, the time or order of their operations being of no consequence. The armature lever of G will first propel the toothed wheel by means of the pallet N. The wheel carries with it the contact arms A B, and the circuit at B C is opened. After the wheel has been propelled far enough for the centering pallet P to slip over the point of the next tooth, contact is made at R. When the armature lever of the magnet H has operated in the same manner contact is made at S, and the index hand with the wheel has been moved one space (say a degree) and in unison with the wheel and index hand of the transmitter. The contacts R S being completed the current is divided, a portion still flowing through the magnets F G H, the remainder through the circuit T and magnet U. The armature lever of U will, near the end of its stroke, hit the bell-crank lever V, throwing the horizontal end up, and thus breaking the circuit from the battery. Before the contact at V can be re-established all the magnets will demagnetise, the armature levers will be drawn by the retractile springs to their normal position. The circuit at B C has already opened by the forward motion of the transmitter wheel M R S, when the armature levers are drawn back and the contact at K is re-established. Last of all, contact V to the battery is made, and the instruments repeat the same series of operations when the temperature rises another unit.



Clarke's Telemeter.

If the temperature falls, the initial contact is made at A C; the circuit containing F G H is opened, the magnets on the other side propel the wheels and index hands; magnet U is connected to battery and circuit at V is opened. Among the mechanical details and methods by means of which the electric circuits are operated, special attention is directed to the following points :—No friction or opposition to the free motion of the initial instrument (thermometer, &c.) is made. It may

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

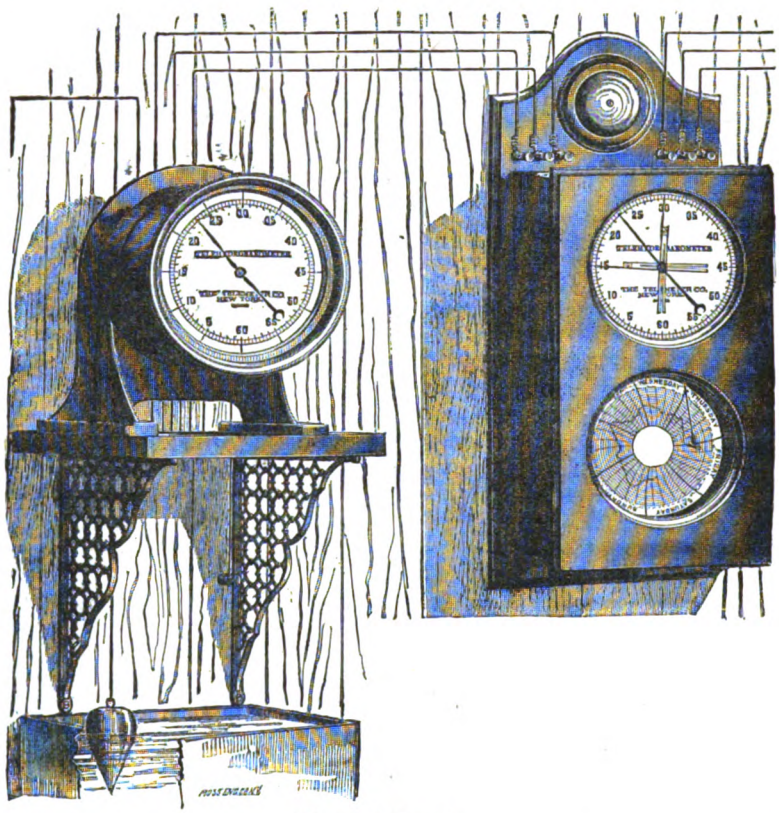
therefore be any delicate piece of mechanism or instrument which can impart motion to a hand (C).

The moment contact is made at B C, the circuit of the opposite side is opened at K. This prevents both sides of the system from acting simultaneously in case a violent blow or jar to the transmitter should cause C to oscillate rapidly, thereby making nearly simultaneous contact on both A and B. As each side opens the circuit of the other, one side must prevail. Without the circuit-opening device at K a rapid oscillation of C would bring both sides into action. The armature levers which move the toothed wheels would oppose each other, consequently the contacts at R and S could not be completed, U would not be connected to battery, the circuit at V would not be opened. The mechanism would remain in this position until the battery became exhausted. The next operation, or closing of circuit at M, not only substitutes a firm contact in place of a delicate contact, but allows the circuit at B C to be opened without spark, the circuit still remaining through M. Another point worthy of attention is that the magnet U being in an independent circuit completed by the final action of both instruments, the circuit is not opened until both instruments have completed the motion of the toothed wheels and index hands; therefore the index hands cannot get out of unison. Special attention has been given to the mechanical conformation of the wheels and pallets, making it impossible for any amount of battery power to cause the wheels to move more than one tooth for each movement of the armature lever. At every point of contact except A B C, one of the contact points is on a flat spring. This prevents any mechanical jar from opening contacts when once established. The springs are also bent, so that in making contact there is a slight rubbing motion. All the magnets have separate shunts connected to their terminals (not shown in diagrams) so that the discharge from the magnets shall pass through the shunts instead of taking place at V. The only spark at V is that due to breaking the battery current. It is exceedingly small and difficult to detect. One of these circuit breakers has been in use in a Time System, operating on the same principle as the instruments above described, and has, up to date, opened the circuit more than one and a-half million times and without any deterioration. Any injury which could occur from the spark is reduced to a minimum by the rapidity and completeness with which the contacts are separated. No spark occurs at contacts M R S, because these contacts do not separate until V is opened, leading directly to the battery.

To sum up, the instruments will work on an open circuit battery, and the wear on the points from electrical discharge has been so carefully looked after that the instruments will remain in adjustment for an indefinite period.

The mechanism which has been described can be used in many varieties of instruments. Mr. Clarke has adapted it to indicating the height of water in reservoirs, or the position of gas tanks; also for indicating steam or water pressure. There are also cases made for the thermometers to adapt it for the various industries in which it may be used.

The instrument is brought before you as a carefully worked out solution of the problem of indicating and recording at a distant point the movement of a revolving hand.



Clarke's Telemeter.

DISCUSSION.

Mr. FRANCIS: I have had an adaptation of these instruments two miles apart for indicating the height of water. I live in Lowell, Massachusetts, where a large number of people use water from mill ponds, and it is important to note the height of the water. One of these instruments has been in use and has answered very successfully. Previous to its employment it was necessary to send up a messenger every half hour from half a mile away. The instrument we put in two years ago in an experimental state, and at first there was a great deal of trouble with it, but for the past year it has answered perfectly. During the earthquake last year in the States, which took place between 9 and 10 o'clock, there was no indication in the neighbourhood excepting in that instrument, which showed that there was a little vibration in the mill pond just at the moment of the earthquake one hundred miles away.

Mr. G. KAPP asked whether the instrument indicated at one degree or stopped at any time.

Mr. UPTON: The movement in the instrument is about a degree and a half.

Mr. FRANCIS: In the instrument which I have, every quarter of an inch is indicated when a change takes place. In our instrument it is quarter-inch heights of water.

Mr. LAW said one important application of this instrument seemed to be the giving warning of the rising of the upper parts of rivers, so that the barriers or weirs might be prepared for passing the water off. An instrument of this sort was very much wanted to enable people to be prepared.

Mr. UPTON said that when the instrument was used to measure the height of water there was a contact which moved by a float. Then of course there was another instrument corresponding to the receiver having a large dial twice the diameter of that shown, giving a wavy line, which represented the quarters of inches. This was a very accurate method of measuring the height of water. One practical point in favour of this instrument was that it ran upon an ordinary Léclanché cell; it was an open circuit instrument, and took less power than was necessary to work an electric

Digitized by Google

bell. He had known a battery used in connection with it to last for eighteen months.

The CHAIRMAN (Major-General Webber): I would ask you to bear in mind that in bringing this example of an important and interesting class of instruments to Europe, and producing it before this Association, Mr. Upton has, we must all think, earned from us a debt of gratitude, because the production of a practical working example must in all cases be far more interesting to a meeting such as this than is the case when the paper is sometimes brought before us in the absence of any particular illustration. There has been one paper in our list which has not been read, though doubtless dealing with a most interesting subject, because of the miscarriage in travelling of the instruments which were to have been used in explanation of the paper. We are most grateful to Mr. Upton, who is much better known in his own country than here, though he has been very often a visitor to this side of the Atlantic; but he is best known as being one of Mr. Edison's most tried and faithful assistants, and when the meeting knows that that is the case I am sure that they will more than ever appreciate the honour he has done us. One word more, and that is this, there will be no harm in closing the meeting of this section to-day by saying how much we appreciate the visitors who come to the meetings of this Association from the other side of the great ocean, and I have the pleasure and the honour of reminding you that the gentleman who spoke a few minutes ago and made those remarks on the subject of Mr. Upton's paper was Mr. Francis, a name which has been wafted to this little country as belonging to one to whom all engineers all over the world should feel very grateful for his works and munificence in connection with that branch of science. I propose, and I am sure you will all join with me by acclamation, a vote of thanks to Mr. Upton.

COMPENSATION OF ELECTRICAL MEASURING INSTRUMENTS.*

BY J. SWINBURNE.

Most instruments used for measuring electromotive forces depend on the electromagnetic effect of the current in a coil of high resistance. As the resistance of the coil varies with the temperature errors arise. Thus, a voltmeter wound with copper wire would be quite useless unless a temperature correction were made every time a reading was taken. Prof. Forbes has proposed to put a carbon resistance in series with a voltmeter, as the resistance of carbon falls as the temperature is increased. The idea of utilising this property of carbon is old, but instruments compensated with carbon have not come into use. Unless a carbon were in a vacuum its resistance would no doubt vary, as the carbon would absorb damp and gases.

The temperature error may be caused by the variations of temperature of the atmosphere surrounding the instruments, or by rise of temperature due to the heating of the coils when in use. The methods to be described in this paper consist of arrangements of wires of different temperature coefficients, so calculated that the reading of the instrument is not affected by reasonable variations in temperature. The electro-dynamometer wound as a voltmeter is the easiest instrument to compensate. Such an instrument consists of a large fixed coil, or pair of coils, with a small moving coil suspended and connected in series.

If the fixed and moving coils are wound with German silver wire, whose temperature coefficient is 0·044 per cent. per degree C., the readings will vary about 1 per cent. from winter to summer. 0·044 is the coefficient generally given in books, but German silver may have almost any temperature coefficient according to its composition. If an idle coil of copper wire is put in shunt to the moving coil, the current through the fixed coil will be divided between the moving coil and the copper resistance. As the temperature rises the current decreases if the electromotive force is kept constant; but as the resistance of the copper coil increases about ten times as fast as that of the German silver moving coil, the moving coil carries a larger share of the current, and the current in the moving coil can thus be made to increase so that the product of the current in the fixed and moving coils remains constant. Such a system does not give perfect compensation, but the error is of a higher order, and through ordinary ranges it is insignificant. This disposition compensates for the variations of temperature of the room, but not for rise of temperature due to the current itself. In a dynamometer-voltmeter this error is too small to be important, but there is no objection to winding the copper wire round the fixed coil so that it is at the same temperature. It may be doubled on itself so as to have no magnetic effect, or it may be wound backwards; but this gives rise to difficulties in the calculations. It would be of little use to work out examples, as the temperature coefficient of German silver varies with the sample. When the coefficent is known it is generally necessary to solve a cubic equation.

A voltmeter, such as a tangent galvanometer with a controlling magnet, may be compensated for room errors by putting a resistance of copper wire in shunt to it, and a German silver resistance in series; the resistances are so calculated that the current in the galvanometer coil is constant. This arrangement of course wastes a little power, but that is not generally a matter of any importance.

Another arrangement was suggested to the writer by Mr. Evershed, who was working with him. Instead of making the copper an idle coil, it may be wound backwards round the voltmeter, the exterior resistance being dispensed with. The magnetic effect is then the difference of the magnetic effects due to the German silver and copper wires. As the instrument heats the current in the German silver wire decreases, but the current in the copper wire decreases much faster, so that their difference remains practically constant. This arrangement is very suitable for low electromotive force voltmeters, but there are difficulties in the way of its use for high electromotive forces. Unless the copper wire is wound with the German silver, so that the two wires lie side by side, it is difficult or impossible to calculate the effects of the wires. If they are wound together, and the copper wire is then connected backwards, neighbouring wires have the full electromotive force to be measured upon them, and the insulation is apt to break down. In addition to this the copper wire has to be very small. Taking German silver as having ten times the specific resistance of copper by volume and $\frac{1}{10}$th of the temperature error, the ampere turns of copper wire would have to be $\frac{1}{10}$th of the ampere turns of German silver wire, so the diameter would have to be $\frac{1}{10}$th. In most cases this would demand a copper wire of from one to two millemitres diameter, which is too small for practical use.

Most Wheatstone bridges are wound with platinum silver wire, and when exact measurements are required, temperature corrections are made. Temperature corrections can be made unnecessary by winding the coils forming the adjustable resistance and the coils of the line side of the bridge with platinum silver, and the coils on the other side of the bridge with wire having twice the temperature coefficient. The coils with double temperature coefficients need not be made of any special alloy, as any temperature coefficient can be got by making the coil partly of platinum silver and partly of copper wire. The bridge still compensates if the galvanometer and battery change places.

The temperature error of a standard cell, such as the Clark, can be compensated. Such cells are arranged in shunt to a resistance which is in series with a larger resistance, which is generally adjustable, and varies from 30 to 60 times the resistance to which the cell is in shunt.

If the adjustable resistances are made of copper and German silver, so as to have higher temperature coefficients than the resistance in shunt to the standard cell, temperature errors of the cell can be eliminated. The adjustable resistance may be made up of ten coils of 1 ohm each and ten of 10 ohms each, 1·438 being in shunt to the cell, and 0·562 between the adjustable resistance and the 1·438 to make the resistance read in round numbers. The ten 10-ohm coils will thus have different proportions of copper and German silver, as their coefficients must be slightly different to compensate throughout the range.

There is another source of error which seems often to escape notice. If an electro-dynamometer is connected up as a watt meter for measuring small powers, such as that consumed in an incandescent lamp, either the pressure coil is in shunt to the lamp, and in series with the current coil, or it is in shunt to both the lamp and the current coil. In one case the current through the pressure coil measures the fall of potential, not only over the lamp but over the current coil also; in the other

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

the current coil measures the current through the pressure coil as well as through the lamp. If all the lamps measured were of the same resistance this would not matter, as the instrument could be calibrated for that resistance, but the error in using the same voltmeter for 50 volt and 100-volt lamps is very considerable.

This error may be eliminated by a sort of differential winding. It is best to fix the current coil and make the pressure coil movable, as there is then less trouble in making the connections. A few turns of small wire, equal in number to those of the current coil, are wound backwards round it and put in series with the pressure coil. The pressure coil is then put in shunt to the lamp only. The portion of the current in the current coil which comes through the pressure coil then has its action neutralised by these backward turns carrying the same current.

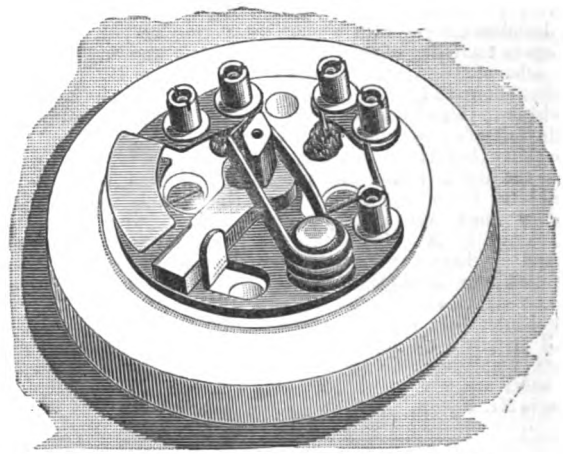
The same method may be applied to volt- and am-meters when used for such purposes as incandescent lamp measurement. If the voltmeter is in shunt to the lamp only, a few turns in series with it are wound backwards round the ammeter. If the voltmeter is in shunt to the lamp and the ammeter, a few turns of the main or ammeter circuit are wound backwards round the voltmeter coil.

AMERICAN EXPERIENCE OF UNDERGROUND WIRES.

During the Boston meeting of the American Electric Light Association some conversation took place on the subject of underground wires. The matter was brought forward by Mr. Leggett, of Detroit, who appealed to the association for advice under the difficulty in which they were placed at Detroit by the order of City Council to place all wires underground. Detroit, as our readers will probably recollect, is lit by the "tower" system, and the length of wire employed exceeds 400 miles. "We have invested," said Mr. Leggett, "nearly half a million of dollars in our plant, and you can readily see that we are driven to an extremity. I must confess that after all our investigations in this matter we are as yet entirely undecided to know what to do. We want to know whether we are obliged to take one of a number of things, each of which is experimental, or whether there is some system which some member of this association can say he has found to be expedient and practicable throughout." Mr. De Camp said that in Philadelphia the city electrical department about a year and a half ago made an appropriation of $5,000 to put down a line about one mile long. "A lead-cased cable was laid, well insulated, put in a trough which was filled up with residuum of petroleum. That carried 12 lights of 30 volts each, which was the extent of that particular line. The cable is working fairly well, but from various causes has had more or less grounds on it—very many more than the overhead circuit. Additional experience was recently had at South-street, where there was a circuit of one mile put in. The first circuit put in was taken up for some reason or other, it being a failure. The cable, which is there to-day, is a good one, but the superintendent tells me that the grounds are so numerous that he hardly knows where he commences to pick them out; and there they are to-day in that condition. Whether it is the fault of the cable or of the conduit or of the work done I do not know. That, however, has brought us to this conclusion, that we have got to replace all of that before we shall be justified in running lines over such a circuit." Mr. Brown said that he had had about eighteen months' experience with underground work in Chicago. "We have there the Dorsett conduit, and are troubled greatly with gas, and have had two or three explosions, although they have not caused much damage. We find that the principal trouble with the conduit is at the joint. We think if a perfectly tight conduit joint could be made that we would not be so much troubled with gas, and even water that leaks in. The newest conduit which we know of in Chicago is the Hurlburt conduit, which has a flexible joint. It has been on the market but a short time, and I do not know that any of it has been laid. But it seems to me that it would carry out the expectations entertained regarding it from the fact that the joint is flexible. We have manholes at an average distance of 400ft. apart, and between the manholes we find that the conduit sags after it has been laid any length of time from the pressure from above—the street traffic. We have some 60 or 70 miles of wire under ground." Mr. Powers, of Troy, expressed a very strong opinion that it was not possible to place electric light wires underground in the present state of the art, especially where lights are spread over a large area. Mr. Law remarked that in Philadelphia they had also had a good deal of trouble from gas leaking into the conduits.

DORMAN AND SMITH'S PORCELAIN SWITCH AND SAFETY FUSES.

Messrs. Dorman and Smith, of Manchester, send for our inspection a specimen of one of their combined switch and safety fuses, mounted and enclosed in porcelain. The interior of the switch is illustrated in the accompanying engraving. It will be seen that it



is fitted with a strong spring throw-off, and has good rubbing contact. In the smaller sizes a porcelain thumb-screw handle is attached to the central pivot (this is not seen in the figure), but in the larger sizes Mr. J. H. Holmes's device of a loose handle is adopted. In this arrangement the hole in the turnkey is made larger than the diamond over which it fits, consequently as soon as the contact piece comes under the influence of the spring, the diamond turns loosely in the key and a quick throw-off is secured irrespective of the speed at which the handle is moved. With the thumb-screw in the small sizes this is not necessary, because the handle easily twists in the fingers. We are informed that large numbers of these switches have recently been supplied for ship-lighting.

We are glad to note the rapidly extending use of non-inflammable switch and fuse blocks for installations of all kinds.

NOTES.

THE CHARGE OF ALTERING TELEGRAMS.—Harry Wilkes, the telegraph clerk who is charged with altering racing messages, has been committed for trial.

EDISON'S PYRO-MAGNETIC DYNAMO.—This machine will be on view in New York at the Exhibition of the Electrical Society, which opens next week in that city.

THEATRE LIGHTING IN LONDON.—We hear that five theatres in the West-end are about to be supplied with electric light by means of Ferranti transformers from the central station at the Grosvenor Gallery.

THE ITALIAN TELEGRAPH SYSTEM.—There are now 2,145 telegraph offices open in Italy, and during the first three months of the present year the number of messages dealt with amounted to 1,847,781, of which 170,469 were foreign.

ELECTRIC CARS IN LISBON.—The Portuguese papers report that Julien's system of electric traction is about to be introduced for the public service by the Companhia Corris de Ferro of Lisbon. Experimental trips were to be made last week.

THE LIGHTING OF OPORTO.—The Portuguese paper, *O'Diario Populas*, says that the Executive Committee of the Municipality of Oporto has been authorised to denounce the contract with the gas company, which will terminate in 1889, and to receive proposals for lighting the city by other means.

PARIS.—It is stated that Messrs. Rothschild, Marcel Deprez, and Gerald are working out a scheme for providing electric light for "the whole of Paris," "the mathematicians of the establishment" having demonstrated, we are told, that such a scheme will prove more economical than that of isolated installations.

LECTURE BY DR. FLEMING.—At the meeting of the Iron and Steel Institute at Manchester, Dr. J. A. Fleming delivered an interesting lecture on "Electric Lighting in Factories." The lecture attracted a good deal of attention among the members of the institute, and it may be hoped will be fruitful in results.

WHAT DOES THIS MEAN?—We quote the following sentence from a paragraph in the *Electrical World* of New York. The italics are our own:—"Such a city as London ought to present a magnificent field for the utilisation of the electric motor, which will certainly very soon come to the front there, *probably in some degree through American enterprise.*"

THE CITY OF LONDON COLLEGE.—The fortieth session of the City of London College, White-street, Moorfields, E.C., commences on Monday, October 3rd. The scientific work of this institution, although of an elementary character, is in excellent hands, and the evening classes in electricity and magnetism probably form as good an introduction to the subject as can be obtained.

BATS.—A new industry has sprung up at one of the American towns in catching bats by electric light. Every night men may be seen around the arc lights in the quieter streets armed with a kind of large butterfly net, in which the bats, dazzled by the light, are easily caught. The market value of a bat is at present about 5 cents. We do not, however, know what is done with them—unless they are served up as game-pie.

ATTEMPTED STORAGE OF ENERGY DERIVED FROM WIND.—The Duc de Feltre has succeeded in persuading the French Government to allow him to try to supply the electric lights at La Héve Lighthouse by means of a battery of accumulators which are to be charged by wind power. The windmill is to drive a dynamo which is to charge the accumulators. The success of the experiment is, we need hardly say, extremely doubtful.

CABLE EXTENSION.—The ss. "Scotia" left Greenwich on the 19th inst., having on board 1,500 nautical miles of cable, to lay a duplicate cable between Gibraltar and Malta, and an extension from Malta to Zante. Mr. Lucas is in charge of the laying on the part of the Telegraph Construction and Maintenance Company, and Messrs. Forde and Taylor and staff represent the Eastern Telegraph Company. This will give the latter company another line between England and Malta.

THE SCIENCE AND ARTS DEPARTMENT.—At the examination in magnetism and electricity, held on the 11th May, 1887, 14,001 candidates presented themselves; of these 12,257 came up in the elementary stage, 1,683 in the advanced stage, and 61 in honours. The results were as follows:—In the elementary stage 1,041 obtained a first class, 5,907 a second class, and 5,309 failed. In the advanced stage 237 obtained a first class, 744 a second class, and 702 failed. In honours no candidate obtained a first class, 5 obtained a second class, and 56 failed.

CATAGRAPHY.—According to an American paper a farmer somewhere out west was recently annoyed by the squalling of some cats in the back yard during a thunderstorm. Going out to quiet them a blinding flash lit up the heavens—the cats were seen no more, but upon the forehead of the unhappy man their portraits had been indelibly impressed. Such stories have been recorded before, and need not necessarily be untrue. In a museum at Washington there is a brass tray upon which the face of a young girl has been stamped by a lightning flash. This occurred about twelve months ago, and we gave the particulars at the time.

AMERICAN PATENT LAW: IMPORTANT DECISION.—According to American patent law, if a patent is taken out in any foreign country *prior* to the granting of a United States patent for the same invention, then the United States patent, at whatever date it may be subsequently obtained, expires at the same period as the earliest of such foreign patents. In a case which recently came before the American Courts it has, however, been decided that for the purpose of the clause above referred to, the date of an English patent is not that of the filing of the provisional specification, but that upon which the patent is sealed. This decision is therefore very favourable for English inventors.

MR. TROTTER'S SYSTEM OF REGULATION.—We mentioned last week that Edison had described a method of obtaining regulations for constant current by a method similar to that described by Mr. Trotter in his recent paper. On further examination, however, we think it only fair to state that it does not appear that Edison had at all clearly conceived the special feature of Mr. Trotter's method, which consists in varying the magnetic susceptibility of the second half of the exciting circuit by varying the exciting power instead of directly varying the magnetic resistance. Edison's ideas branched out in various directions, but it is not at all clear that he had perceived the advantages of the method now described.

EARLY SUGGESTIONS FOR ELECTRIC WELDING.—In the *Manchester Memoirs*, Vol., XIV. p. 49, Joule has a note "On the Fusion of Metals by Voltaic Electricity," in which he speaks of the advantages of electric welding if current could be supplied economically, and describes some experiments made with iron wire. Joule calculated that, using a primary

Digitized by Google

battery, the quantity of zinc consumed in the voltaic process is nearly equal to that of the iron to be melted. He concluded by pointing out that "it would be possible to effect the same object in a more economical manner by availing ourselves of the use of the magneto-electrical machine, and that 5,000 grains of coal used in this way would suffice for the fusion of one pound of iron."

VACANCY FOR ELECTRICIAN IN THE COLONY OF BRITISH GUIANA.—The following notice appears in the *Post Office Circular* of September 20:—"A vacancy for an electrician has occurred in the Colony of British Guiana. Salary £350, by £10 per annum to £400. Deduction of 4 per cent. from salary towards widows' and orphans' fund. Pension of one-fiftieth of salary for each year of service after ten years' service and fifty-five years of age. When travelling on duty in the colony the electrician is paid actual travelling expenses, and a personal allowance of 16s. 8d. a day when absent from fixed residence. At the request of the Secretary of State for the Colonies applications for this situation are invited. The officer selected will be required to take technical charge of the Government land lines and cables, under the superintendence of the Postmaster-General of the Colony."

NEW SPANISH TELEGRAPH SYSTEM.—It is stated by the Madrid paper *El Dia* that the system of duplex telegraphy invented by the Spanish telegraph official, Señor Perez Santano, has been definitely installed between Madrid and Valencia. According to the same paper, Señor Santano is represented by the consultative Board of Telegraphs to have added a "brilliant page to the history of telegraphy by his invention." Another journal, *Las Ocurrencias*, in dwelling upon the advantages of the system, says that in a line of 360 kilometres, which is the length of the Valencia line, with a capacity of 1·50 microfarad and an approximate resistance of 4,000 ohms, the duplex system works without condenser or compensation of any description. "And if to this," says the journal in question, "be added the fact that the Morse system can be converted into 'Santano' without incurring the expense of a single centime, it will be recognised how transcendental is the service rendered by Señor Perez Santano to his country." Experiments were shortly to be made upon the copper lines between Madrid and the French frontier.

ATLANTIC CABLE RATES.—The following circular letter, not wholly unexpected (says the *Electrical World*), was issued on September 1 from the executive offices at No. 40, Wall-street, of the Commercial Cable Company (Mackay-Bennett cables):—"To the Patrons of the Commercial Cable Company: On and after September 15, 1887, our tariff will be 12 cents per word to Great Britain, Ireland, and France, and 15 cents per word to Germany. We have in justice to our patrons decided upon this reduction in order to give them the benefit of the lowest rates during the time the tariff war may last. We sincerely thank our friends for the hearty support they have so steadily given us, and believe the cabling public will see it to be to their interest to favour the Commercial Company with a continuance of their patronage.—George G. Ward, Secretary and General Manager." Vice-President Hector De Castro, of the Commercial Cable Company, said that the reduction had been made from 25 cents a word not because of lack of business, for the patrons of the company had stood by it nobly, but simply because it was the fair thing to do.

THE GENERAL ELECTRIC APPARATUS COMPANY'S CATALOGUES.—The General Electric Apparatus Company send copies of a new edition of their illustrated catalogues. The electric bell catalogue contains a long list of bells, indicators, batteries, and accessories, together with a very complete set of instructions and diagrams showing the different methods of making the connections. This should be especially useful to amateurs and others who wish to connect up their own bells. A second catalogue of the same firm is devoted to "electric lighting plant and material," and contains a list of engines, dynamos, accumulators, transformers, switches, cut-outs, main and branch leads, arc and incandescent lamps, holders, fittings, ammeters, voltmeters, glass-ware, and wood-casing, &c., &c., &c. This enumeration will sufficiently indicate the exhaustive character of the list, and with respect more particularly to certain of the minor appointments, such as glass-ware and fittings, it may be remarked that the company has been successful in introducing some novel and improved types. The catalogue will be of service to all interested in electric lighting.

ELECTRIC LIGHTING OF THE MANCHESTER THEATRES.—A correspondent of the *Manchester Guardian* writes as follows:—"Less than two years ago we had two theatres—the Royal and the Comedy—in Manchester lighted by electricity. The electric plant was in an adjoining warehouse, and the installations appeared to give every satisfaction. This has been discontinued and lighting with gas resumed. Surely now that we have received so terrible a warning against the use of gas in theatres the managers will see their way to resuming the electric illumination, as many people are deterred from entering the buildings by the manifest danger, in spite of the great attractions now offered." The installation referred to was carried out by the Manchester-Edison Company, current being supplied from a central station at a rate equivalent to gas at the Manchester price, which is, we believe, about 2*s.* 8d. per 1,000 cubic feet. The installation was entirely successful; but naturally it was not a paying speculation, and failing to obtain a better price the company were no doubt well advised in discontinuing the service, which they did in April or May of the present year.

TENDERS REQUIRED FOR TELEGRAPH POLES AND CREOSOTING.—The Postmaster-General is advertising for tenders for the supply of 7,710 red fir telegraph poles to be delivered in London, and 16,955 to be delivered at Northumberland Dock (River Tyne) or West Hartlepool. The poles to be felled between 1st November, 1887, and 28th February, 1888, and to be delivered during the following summer. Tenders are also invited for creosoting the above-mentioned poles with either 8lb. or 10lb. of creosote to the cubic foot, as may be decided hereafter. Tenders may be submitted for either (A) the supply of the poles; (B) both the supply and creosoting; or (C) the creosoting only; but if (B) be tendered for, tenders for (A) and (C) are also requested. Any person tendering, who has not previously supplied the Postmaster-General with poles, must submit thin butt sections from not less than three different poles, to show the quality of timber offered. Forms of tender, containing all particulars, may be obtained on application, either personally or by letter, to Mr. W. H. Winter, controller of stores, Telegraph-street, London, E.C. Tenders will be received by noon on 24th October.

POST OFFICE TELEGRAPHS.—In his thirty-third annual report for the year 1886-7 the Postmaster-General remarks, with reference to the telegraph service:—"The first complete financial year during which the reduced rates for inland telegrams were in operation expired on the 31st of March, and it is interesting to note the effect upon the number of messages and upon the revenue. Separating the ordi-

Digitized by Google

nary inland messages sent in that period from railway, press, official, and foreign telegrams, which are not affected by the reduced rate, and of which there were over ten millions, it appears that the number of messages despatched was 40,137,175 in 1886-87, compared with a total of 30,087,869 in 1885-86, and that the revenue produced was £1,354,879, as compared £1,277,606 in the previous year, showing a growth of over ten millions, or 33 per cent. in the number of messages, and over £77,000, or 6 per cent. in the revenue. The London local messages alone show an increase of 50 per cent., the total number being about 3,800,000. The expenses of this service, however, far exceed the receipts, and the deficit, after including the interest payable for the capital borrowed, amounted to £469,840."

LIGHTNING CONDUCTORS.—Dr. J. A. Fleming writes as follows to *The Times* on the subject of lightning conductors:—"May I be permitted to add one word to what has been already said by your scientific correspondents in caution to those having structures under their care not already properly protected from lightning? Not only is it necessary to have a properly fitted conductor or system of conductors to every valuable building, but it is above all things necessary to have a periodical electrical test applied to the conductor in order to ascertain if the earth plate is making 'good earth.' The proper manner of doing this is to run a second isolated cable parallel to the conductor and making contact with it near the top. This testing cable should have a separate earth plate. A simple electrical test, applied easily, will then enable an observer to state whether that conductor is an efficient lightning protector, or only an additional source of danger. I venture to think that of our English cathedrals and public buildings having more or less imperfect lightning protection, not one in a dozen is ever inspected, tested, or certified to as secure by a competent authority. Every lightning conductor should be properly tested once a year at least, and a certificate of the test furnished to those responsible for the building."

SOME BELGIAN TENDERS.—For the electric lighting of the military hospital at Ixelles, near Brussels, the following tenders were received:—

	Francs.
Société Electricité et Hydraulique of Charleroi.	67,200
Société Bouckaert et Cie. of Brussels	68,200
Société Phœnix-Edison of Ghent	68,300
Société Industrielle d'Electricité of Brussels ...	73,000
Société L'Electrique of Brussels	74,100

The first-named tender (which has been accepted) includes the superintendence of the installation during the first twelve months.—A contract has been signed for lighting the railway station of Meirelbeke, Ghent, by Messrs. Bouckaert and Co., who represent the German firm of Schuckert and Co. Twenty-four arcs of the Krisik type of 600 candle-power are to be used. The installation is to be worked by the contractors under the following tariff:—0fr. 54c. per lamp-hour for the first 3,000 lamp-hours; 0fr. 48c. for the succeeding 500 lamp-hours, and 0fr. 40c. for the remainder.—Our Brussels correspondent informs us that a good deal of work is being carried out in Brussels and the neighbourhood. The premises of Messrs. Hirsch, in the Rue Neuve, are being supplied with 300 incandescent and 40 to 50 arc lamps. A steam engine of 80 horse-power is provided, driving two dynamos delivering 150 amperes at 100 volts.

TELEPHONIC COMMUNICATION IN MID-LOTHIAN.—The Mid-Lothian County Road Board have, it appears, decided that "with the view of commencing a system of telephonic communication throughout the county" permission shall be granted to the National Telephone Company "to place certain lines of communication through the eastern part of the county, with two call boxes," as also "a short line from the western confines of the company to the Oakbank Oil Company's Works, with a subordinate call box at Mid-Calder." Mr. R. A. Macfie, of Dreghorn, has issued a printed statement to the members of the County Road Trust (whose confirmation he understands is required in the matter), in the course of which he indicates certain objections to the above decision of the Board as it stands, and suggests that the question should be reconsidered. He specifically complains that they "have left the whole areas of the water of Leith above the city and the Upper Esk, and such important and populous places as Corstorphine, Juniper Green, Lasswade, Liberton, Loanhead, Midcalder, Pathhead, Penicuick, and Slateford unprovided, and have also made it very improbable that any other company will enter the field, thus constituting practically a very valuable unlimited monopoly." Decidedly we are getting on (in Scotland at least) when Juniper Green has a grievance in the lack of telephones.

CHINESE TELEGRAPHS.—It is stated that the very first operation of the American syndicate which has obtained concessions from the Chinese Government will be the establishment of long-distance telephone lines between all the chief cities of the country. It is known that a considerable number of land lines already exist in China, and of late years have been rapidly extended, chiefly under the supervision of some Danish engineers. The first line was that between Hong Kong and Shanghai—chiefly submarine—which was opened in 1873. The Chinese having no alphabet, it is the rule to translate native messages into some European language and retranslate at the other end. Upon the land lines, however, a mercantile code, containing 7,000 terms in common use, has been compiled by the Chinese authorities, the words being indicated by a number placed opposite each character. This system has proved itself fully competent to deal with the present amount of traffic, but it is obvious that with the awakening of the country, which seems now to have set in in earnest, it will have to give way to some more rapid process. Unless the Chinese follow the example of their neighbours the Japs, and learn English wholesale, it is probable that the telephone, or perhaps the writing telegraph, will prove the most rapid means of communication available. Even at the most reckless rate of progress it will be some years before they feel the need of a Wheatstone automatic at 450 words per minute.

SOME PROPHETIC ELECTRIC LIGHT FIGURES.—Our monthly contemporary, the New York *Electrician*, has the following cheerful forecast of the future of electric lighting in the States:—"Now that modern improvements in the methods of distributing electricity for incandescent lighting have rendered it practicable to establish and maintain central station plants at a profit, even in towns of not more than 4,000 inhabitants, it has become possible to ascertain with some approach to accuracy the dimensions of the field which is open to be occupied by this incomparable illuminant. Experience shows that when house-to-house lighting has been thoroughly worked up in any town, the capacity of the central station plant will need to be equal to an average of about one 16 candle-power lamp for each inhabitant. According to the census of 1880, of the 50,000,000 inhabitants of the United States, 13,000,000 or 26 per cent., resided in 580 towns and cities having a population in excess of 4,000 each. At the normal rate of increase we shall have, in five years from the present writing, a population of nearly 70,000,000, of whom some 18,000,000 will be gathered within the limits of towns

Digitized by Google

of 4,000 inhabitants and upwards. Each of these individuals will represent one incandescent lamp and the necessary power for operating the same. Even after deducting the lamps which have already been installed, there will be required a total output of more than 11,000 lamps and over 1,000 horse-power each of steam-engines, boilers, and dynamos, every working day for the next five years to supply the demand which from all present appearances will inevitably arise. This is entirely aside from the additional number of lamps which will be required for renewals—itself an enormous item. The change from gas to electricity which is now going on in connection with domestic lighting will be not a little accelerated by the action of the gas companies, who are everywhere evincing an increasing disposition to take up electric lighting themselves; and a very sagacious policy it is, too, in view of the present outlook for gas illumination."

BERLINER'S "ELECTRIC FURNACE GENERATOR."—The *Electrical World* of the 10th inst. contains a letter from a solicitor in America enclosing a copy of a specification filed by M. Emile Berliner, on June 18th, 1885, describing an "electric furnace generator," which is in principle substantially the same invention as Edison's pyro-magnetic dynamo. The letter contains the following passage:—"You will notice that the numerous suggestions of modifications which appear in the specification contain the germs of valuable improvements upon the original apparatus, and those who know the untiring productiveness of Mr. Berliner will at once understand that these germs were not allowed to die for want of nourishment. Mr. Berliner freely communicated his original ideas to other electricians at an early period; he invited them to join in his work, but they declined, and, in one remarkable instance, at least, upon the ground that the invention was completed, and that there was no room left for the elaboration of the original idea. . . ." The writer is careful to exonerate Edison from a knowledge of these facts. The apparatus devised by M. Berliner is constructed as follows: A magnetised steel cylinder with a some what narrow bore is surrounded with a coil of wire insulated with asbestos or some other fire-proof substance. The cylinder is set upright over a furnace, and its lower end is closed by an iron plate, against which the heated gases play upon the lower side. To the upper end of the hollow magnet a flexible tube is attached, with which a pair of bellows is connected. Each time the bellows is compressed the current of cool air increases the magnetic susceptibility of the iron plate which acts as an armature, and a current of electricity is consequently induced in the coil. The specification concludes in the following terms:—"The current thereby produced might be utilised to charge another coil surrounding the magnet and re-enforce the magnetic field; and in that case the magnet might be substituted by a tubular core of iron; the bellows might be dispensed with, and a constant source of compressed air might be employed, regulated by suitable mechanism to supply the air puffs to be directed against armature K, or even pieces of cold metal might be made to approach the armature at intervals, and cool it by contact with the same; or by absorption and radiation; or a series of coils and magnets might be placed towards one larger armature disc forming a common armature, heated by one furnace. All these ideas can be brought to bear on the subject whenever time offers itself to experiment, which is the most effective modus. For the present, I claim: The combination with the magnetic field and a conductor situated therein, of a piece of iron which is alternately heated and cooled, thereby producing electricity, substantially as described." It is evident that the weak point of this arrangement, in comparison with Edison's, is the employment of an open magnetic circuit.

ELECTRICITY OF CONTACT OF GASES WITH LIQUIDS.—Mr. J. Enright replies (in *Nature*) to Dr. Oliver Lodge's criticism as follows:—"May I be allowed to reply to Dr. Lodge? That the escaping gas was charged was proved (1) by *collecting* it in an insulated vessel; (2) by *generating and collecting* it in insulated apparatus. Electrification resulted in the first case, but not in the second. Details of these experiments I intend to publish later. With all possible respect for Dr. Lodge I cannot accept his explanation of the electrifications I have described. I fail to see any analogy between Armstrong's machine and the experiments with zinc and hydrochloric acid which I have made, except, indeed, that, as I hold, they are all cases of contact electricity. Sir W. Armstrong directs a jet of steam against solid wood grooved and shaped to increase the surface of contact. In my experiment, on the contrary, I find that the effect is distinctly lessened when the hydrogen passes through narrow tubes or openings, and accordingly the strongest deflections are obtained when a large open dish is used. I take an evaporating dish, 8 or 10 inches in diameter, and put a small quantity of a 10 or 16 per cent. solution of HCl into it. The acid is at every point at least 4 or 5 inches distant from the edge of the dish. When a small fragment of zinc is thrown in a gentle effervesence is set up, the hydrogen shooting straight up through the middle of the liquid into the air. I submit that in this experiment whatever electrification results is due to gas and liquid, and not to gas and solid. Moreover, after a lapse of a few minutes, when a sufficient quantity of $ZnCl_2$ gets into solution, the charge on the dish changes its sign. Is Armstrong's machine also in the habit of reversing itself? On this reversal of the electrification I base my case. The dish does not vary, but the liquid does, and its variation is accompanied by a change in the sign of the charge. With regard to the atomic charges I do *not* hold that the charge on the hydrogen has anything to do with them. It is true that at first I set out to inquire as to the equality of these charges, but when I found that the charges on the evolved gas and the generator were of opposite sign, I was constrained to admit that the electrifications were not connected with the atomic charges as I had, during the earlier experiments, supposed. Had I found things the other way—that is to say, that the charge of the gas had been of the same sign as the charge on the generator—I should not have thought it at all improbable that the electrifications were due in some way to atomic charges. In fact, at the outset this is exactly what I thought I might possibly fall upon. However, the unexpected occurred. 'But that a gas should be thus electrified strikes one as improbable.' Can this be so? Surely the distinguished champion of the 'air effect,' who has so stoutly maintained that the contact of copper or zinc with gas gives rise to a difference of potential, cannot consider it very improbable that the contact of a gas and a liquid should produce a similar effect. Perhaps it is well to remember that the hydrogen in these experiments is in the nascent state."

ANOTHER EDISON SWOOP.—A good deal of genuine consternation has been created in electric lighting circles in the United States by the issue to Mr. Edison on 30th August of an extraordinarily sweeping patent for which he had applied as long ago as Feb. 5, 1880. The motto of the American Patent Office is usually "slow and sure," but a delay of seven years between the application and issue of a patent is surely unprecedented. The specification aims at nothing short of covering the whole ground of the utilisation of electrical devices connected in parallel to the source of electricity. The

Digitized by Google

claims are eight in number. The first two are as follows:—"(1.) In a system of electrical distribution the combination, with a complete or round metallic circuit, of a number of generators connected in multiple arc with such circuit, and consisting each of an armature revolving in a magnetic field, and a number of translating devices also connected in multiple arc with said circuit, substantially as set forth. (2.) In a system of electrical distribution, the combination, with a complete or round metallic circuit, of a number of generators connected in multiple arc with such circuit, and consisting each of an armature of low resistance revolving in a magnetic field of great strength, and a number of translating devices, also connected in multiple arc with said circuit, substantially, as set forth." The third claim sets forth (in language now quite archaic) the use of shunt wound machines upon such circuits. The fourth claim is broadly for the use of a regulator. In the specification several means of regulation are described, but they are not of an automatic character. The fifth and sixth claims are for the employment of "pressure indicators" for the indication of difference of potential at various points upon the mains. The seventh and eighth claims are as follows:—"(7.) In a system for the generation and distribution of electricity for light or power through cities or towns or districts thereof, a central station whereat are combined a number of generators of electricity connected in multiple arc, and consisting each of an armature revolving in a magnetic field, an indicator of the electric pressure, and a regulator of the current generated, conductors forming complete or round metallic circuits leading from such station to distribute the current throughout the system, and translating devices connected in multiple arc with such conductors, substantially as set forth. (8.) In a system for the generation and distribution of electricity for light or power through cities, or towns, or districts thereof, a central station whereat are combined a number of generators of electricity connected in multiple arc, and consisting each of an armature revolving in a magnetic field, an indicator of the electric pressure, and a regulator of the current generated, conductors forming complete or round metallic circuits leading from such station to distribute the current throughout the system, translating devices connected in multiple arc with such conductors, and meters at the houses for measuring the current supplied to such translating devices, substantially as set forth." According to this the Edison Company actually possesses in America the sole right to every known system of electric lighting except those which depend on simple series connection. Continuous current systems, alternating current systems, direct or indirect supply, secondary batteries, transformers (if in parallel), all seem to come within the comprehensive grasp of these overwhelming claims. We shall await the development of the situation with considerable interest. Meanwhile it may be as well to add that a somewhat similar patent is said to exist in this country. The date is 1881, and it has recently been renewed.

MAGNETISM AND WATCHES.—At the July meeting of the Electric Club of New York, a paper was read by Lieut. F. W. Toppan, U.S.N., entitled "Recent Scientific Discoveries relating to the Effects of Magnetism on Marine Chronometers and Watches." After an interesting account of the evolution of the chronometer (for which the credit rests chiefly with John Harrison, who died in 1766), Lieut. Toppan said: "The chances of injury to chronometers, and to watches especially, by magnetism have been greatly multiplied by the development of the dynamo and its extensive application to electric lighting and other purposes; so it is very common to find magnetised watches in the hands of persons having no connection whatever with electrical appliances. A watch readily becomes sufficiently magnetised to derange its action and render it entirely unreliable. If the regulating part of a chronometer or watch—that is to say, a balance, together with the hair spring—should be badly affected by magnetism, which happens very often, it is clear that the time-piece will suffer more or less, according to the fineness of construction and delicacy of adjustment. Various metals have been suggested to take the place of steel, but it seems to have been left to Mr. Paillard, of Geneva, after fourteen years of experiment, to finally succeed in discovering and producing, in an alloy of palladium, a metal which is uninfluenced by magnetism or corrosion, and still retains those properties necessary to obtain the finest adjustments for changes of temperature. Balances and balance springs made of this alloy are of an expansive property and a specific gravity slightly in excess of steel, but possessed of the very important qualification that it retains its elasticity in heat in a high degree, as verified in observatory trials in various countries, thus reducing one of the worst errors, inherent to a steel balance and spring, aside from its magnetic and oxydable properties, giving us a material which enables us to get a compensation approximating accuracy for a wider range of temperature. Palladium is a metal of the platinum group, and was discovered by Woolston in 1803. Its specific gravity is 11·3, that of gold being 19, steel 7·7 and palladium alloy 8·5. It is more fusible than platinum and melts easily before the oxyhydrogen blow-pipe at 2,840deg. Fahrenheit. In its pure state it is not so ductile as platinum. In producing his balance Mr. Paillard used two different alloys of palladium having a differential expansive ratio in similarity to that of steel. In so doing he at the same time gave us a superior balance, for the two metals composing the laminæ of his balance are congenial, both being made of a palladium alloy and being fusible under different degrees of heat, having the necessary hardness and other qualifications. Numerous searching tests with balances in connection with the palladium alloy springs have given the most flattering results, and we have in chronometers and watches containing these balances and springs superior time-keepers uninfluenced by the hygrometric condition of the atmosphere or any spasmodical electrical condition of the same, and excelling all previous attainments with the steel and brass balance and steel balance spring. This question of magnetism and the necessity for protection of chronometers and watches against magnetic influences has called forth inventions of machines and devices for demagnetising time-pieces that had become affected; also a sort of soft iron shield or armour for enveloping the watch movement, as a defence or preventive against magnetic influences. These are mostly cures after harm has been done. There would be no need of these devices if those parts of the chronometers and watches which control the time-keeping qualities were made of metals absolutely unaffected by magnetism, and yet possessing the other necessary qualifications. In the face of the certain fact that electrical appliances shall become wider and wider in their range, and the aggressive tendency of electricity for lighting and as a motive power, both at sea and on shore, we must be prepared to meet its magnetic influence at every step in our industrial occupations. In the discovery of this alloy of palladium a time-piece has been produced that is strictly non magnetic and non-oxydable, and possessing those requisite and necessary qualities for fine and accurate adjustments to temperature and isochronism, and will take rank among inventions of the highest order in horological science."

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 339.)

The action brought by the United Telephone Company against Harrison, Cox-Walker and Co. will long be cited as one of the most remarkable trials of patent law on record. The magnitude of the interests at stake, the perplexity and delicacy of certain of the questions involved, the singularly conflicting nature of the scientific and historical evidence, and the immediate interest felt by the public itself in the issue, all contributed to render the trial a memorable one.

The case came before Mr. Justice Fry on the 24th April, 1887. The plaintiffs sued for an injunction and damages against the defendants on the grounds of an infringement of the Bell patent, by the sale and usage of instruments known as the Cox-Walker and the Hickley receiver, and of an infringement of the Edison patent by the Hunnings transmitter. The defendants did not deny having made and sold the instruments complained of, but the defence set up alleged, (1) that the patent was invalid by reason of the description and exhibition of the Bell telephone at Glasgow in September, 1876, and by reason of the disclosure of the principle in certain publications which reached this country from America prior to the date of the patent; (2) that the invention had been anticipated by the instruments of Phillip Reis. With regard to the Edison patent it was further alleged (3) that the Hunnings transmitter involved a distinct principle of working not described or discovered by Edison, and also (4) that the Edison patent was void by reason of the inclusion in the specification of an invention (that of the phonograph) not properly described in or covered by the title. There were also, of course, numerous minor allegations on the part of the defendants into which we need not enter particularly.

So far as this defence rested upon grounds of pure accident or oversight on the part of the patentees it is scarcely calculated (especially at this distance of time) to enlist much sympathy. The defendants were, of course, legally entitled to benefit by all the mistakes of their opponents; but if the monopoly had been overthrown by this means it would have been a victory of the least satisfactory kind.

In the brief historical *résumé* which is all that these papers aim at affording it is unnecessary to go in detail over the evidence and arguments advanced by either side in a trial which lasted the greater part of a week; and we have merely to summarise the leading points. Taking these in the order already cited, we have, first, the contention of the defendants that the instrument had been publicly exhibited by Sir William Thomson at Glasgow in September, 1876 (the date of the Bell patent being the 9th December, 1876). The circumstances of the alleged publication were these:—At the Philadelphia Centennial Exhibition in August, 1876, Prof. Graham Bell exhibited his telephone while it was yet in an incomplete stage, and, amongst others, to Sir William Thomson. The transmitter consisted of a membrane of skin or parchment, which carried an armature in the form of a flat thin piece of steel spring; the receiver was a hollow cylindrical magnet, with a central core having a flat steel tongue projecting over the core. This armature was not mechanically attached, but was held in place by the magnetic attraction of the core. Its action, as might be supposed, was somewhat feeble and uncertain, but Sir William succeeded in hearing a few words. A little later, on leaving Boston, Prof. Bell placed in his (Sir William's) hands a brown paper parcel, which proved to contain the instruments on which the defendants now relied to upset the patent. There was, however, a not unimportant difference between this receiver and the one at Philadelphia. The armature in this instrument had become a circular plate or disc which was attached to the top of the cylinder by a screw, and was tilted up at a certain angle from the plane of the top of the magnet. On arriving at Glasgow the behaviour of the apparatus caused a good deal of perplexity, both to Sir William and to the assistants in his laboratory. In fact, they could not induce it [no pun intended] to utter a word. The secret, although it eluded even Sir William Thomson at the time, is now easily explained. The fact is that when such a receiver is *pressed tightly* against the ear so that the armature is brought up much closer to the magnet, and also *held down more or less all round*, it then becomes capable of transmitting speech. So long as it was thought necessary to allow the armature to remain loosely attached at one point and tilted away from the magnet its action as a telephone receiver must obviously be imperfect in the extreme.

In September of the same year the meeting of the British Association was held at Glasgow, and Sir William Thomson, in an address to one of the sections, referred to the Philadelphia experiments, and exhibited the instruments he had brought with him, although no attempt was made to use them in public. These were the facts substantially admitted on both sides, the contention of the plaintiffs being that the Glasgow receiver was not a successful invention, that it was not until Bell had made the additional discovery of the immense superiority of a disc clamped all around its edge that a practicable receiver had been produced, and that therefore the description and exhibition of the Glasgow receiver did not constitute publication of the essential principle of the Bell telephone. The defendants were now apparently placed in the anomalous position of having to maintain the success and value of an invention which they had appropriated; but in reality they got over this difficulty by reason of the second branch of the defence, in which it was argued that the Bell telephone had been forestalled by Reis. In order to prove the actual utility of the Glasgow receiver the defence relied chiefly upon the evidence of Prof. Silvanus Thompson who had constructed a working instrument on these lines. This receiver was exhibited in court, and experimented upon by the judge, who was able to hear articulate speech from it. The defendants, moreover, argued that the armature was never intended to be tilted up; that this peculiarity in Sir William Thomson's instrument must have been the result of mere accident. In this they were supported by the evidence of the mechanic who had made some of Bell's instruments at Philadelphia, and who understood that the disc should lie flat upon the magnet. The point was evidently one of considerable importance, though it lay open to the obvious rejoinder that in the understanding of those to whom the alleged "publication" was due, the tilt was taken to be an essential feature of the apparatus and was always so described.

The decision of the learned judge upon this point was against the defendants. "There is no doubt," said Mr. Justice Fry, in delivering judgment, "that some of the most competent and skilled persons who saw it, like Sir William Thomson, came to the conclusion that the disc was intended to be so used, and that the tilt was part of the design and intended structure of the instrument." And the learned judge went on with considerable acumen to point out that this was not surprising, considering that up to this date almost all experiments of this kind had been made with free reeds, which were supposed to be capable of more delicate response than tympans. The value of Prof. Silvanus Thompson's experiment was, in the opinion of the judge, discounted by the fact that the tilt was not so great as in the Glasgow instrument, and that it had only been worked with a carbon transmitter, an appliance unknown in 1876. The judgment (upon this particular issue) was concluded in the following terms: "The burden being on the defendants to show that the anticipation of the Bell receiver by the Glasgow receiver was by an instrument practically as good as the patented one, and of an invention which had passed beyond the stage of mere experiment, I think that they fail in discharging that burden."

There remained a further objection of the same nature—namely, that prior to December, 1876, the invention had been disclosed in this country by the publication of articles both in the English and American press. This was in part true. The *Philadelphia Press* of July 9th, 1876, contained a description of the membrane type of receiver, and in the following August a similar paragraph appeared in the *English Mechanic*. This was the instrument subsequently known to fame as the *English Mechanic* receiver.

It had, however, been clearly shown that the apparatus

Digitized by Google

belonged to the experimental stage of the invention and had been abandoned for the superior and more simple type in common use. The plaintiffs had consequently been permitted on 13th Feb., 1876, to disclaim this portion of the specification without prejudice to the remainder of the claims. This objection of the defendants had therefore no *locus standi*.

(To be continued.)

THE WESTINGHOUSE DYNAMO.

The information concerning the Westinghouse alternate current dynamo which has hitherto reached this country has been somewhate incomplete and indefinite, but we are at length enabled to put before our readers a tolerably complete description of this machine.* When it is stated that the Westinghouse dynamos, although only introduced in the autumn of 1885, are now at work in no less than twenty-seven central lighting stations in the States, supplying 72,000 lamps, it must be admitted that considerable interest attaches to the design.

This machine was devised by Mr. W. Stanley, of Pittsburg. Its external appearance is shown in Fig. 1, Fig. 2 is a longi-

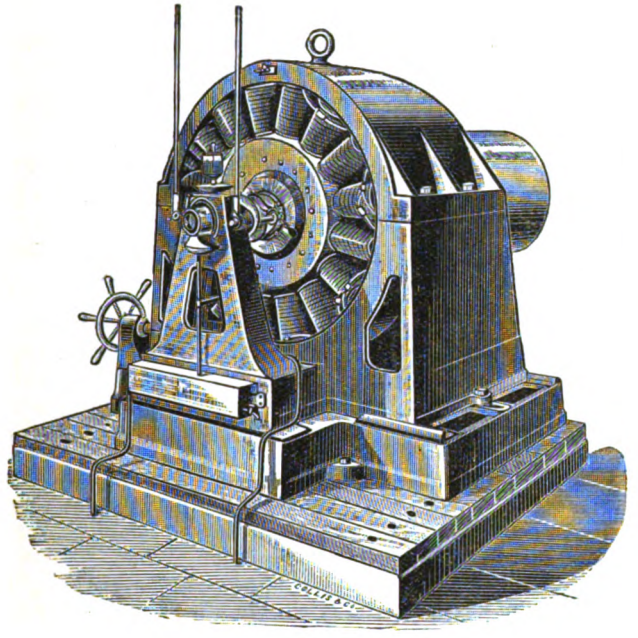

Fig. 1.

tudinal section, Fig. 3 represents the exciter. The foundation of the machine is a heavy cast-iron bed-plate, having projections upon which the standards of the armature shaft are supported. These standards are an integral portion of a single casting, which rests upon the bed-plate, and is held in position by bolts passing through slotted holes, by the aid of which the driving belt may be tightened up by the hand-wheel. The cores of the 16 inwardly projecting field-magnets are fixed to a circular yoke, the lower half of which is formed by the casting just described, and to which the upper half is bolted. The poles, as a matter of course, are of alternate polarity.

The armature is cylindrical in form, and the core is made up of a great number of discs of thin rolled iron placed side by side and insulated from each other by paper. Each plate has six large and a number of smaller holes punched in it for ventilation, and in putting the core together care is taken to keep these holes in line. The discs are clamped together by thicker end plates, which are seen in Fig. 1. The armature winding is somewhat peculiar. First of all, along the periphery of the cylinder are fixed a number of insulating strips which project like Pacinotti teeth, and are secured at either end, where they overlap. The wire is then wound around these strips across the face of the cylinder parallel to the axis, while each turn passes at either end under the insulating strip, so that at the bend it lies in a plane at right angles to the line of the shaft, or, as it may more simply be stated, the ends of the core are bent over parallel with the *end* plates of the cylinder. Each coil, it will be understood, is separately wound, and lies on the outside of the cylinder, as in the obsolete

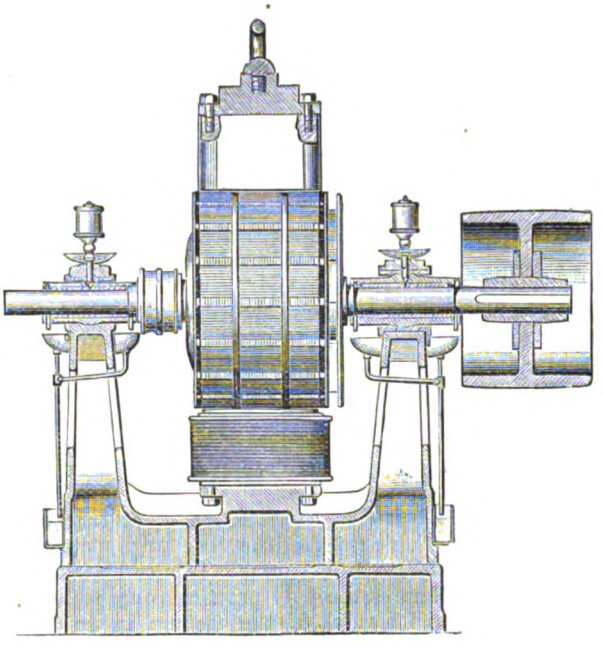

Fig. 2.

Elphinstone-Vincent machine. We have been careful in explaining this point because it does not appear in the illustrations. Washers are fixed to the ends of the armature to prevent the external plates from touching the wire. The outer

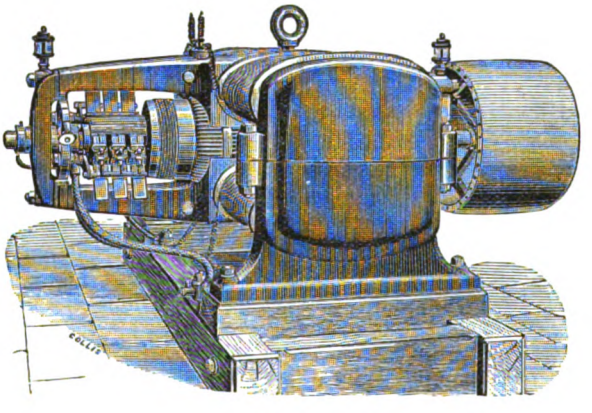

Fig. 3.

surface of the wire is then covered with sheets of mica, and the whole is finally wrapped with two parallel bands of binding wire, wound circumferentially. This is plainly seen in Fig. 2. The connections of the armature are practically the same as in the Siemens machine, and may, of course, easily be varied for different E.M.F.'s. The total weight of a machine of the size illustrated, which is rated at 650 16 candle-power lamps, is 5,000lb. It is run at the comparatively high speed of 1,650 revolutions per minute, and though we have not got the dimensions of the armature before us, we believe that we are correct in saying that the peripheral velocity amounts to somewhere about 8,000ft. per minute, a figure which we need hardly say is considerably higher than that which obtains in English

* Our illustrations are taken from an article in the *Electrical World* of September 3rd. Some information has also been obtained from a paper by Mr. F. L. Pope in the New York *Electrician* for the present month.

Digitized by Google

practice. The E.M.F. ordinarily employed upon the transformer circuit is from 1,000 to 1,100 volts.

The exciter is a Stanley machine, shunt-wound, of which we have at present no further particulars. It is stated that only 2 per cent. of the total electrical energy produced is required for excitation. This is, of course, the result of the high speed employed.

CORRESPONDENCE.

INCANDESCENT LAMP MANUFACTURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Now that Mr. Swinburne appears to have concluded his very interesting series of papers on the manufacture of incandescent lamps, I suppose the subject may be considered as being fairly opened for discussion in your columns.

As there are several matters upon which opinions may differ in regard to detail in this manufacture, and as I have had a good deal of experience in connection with it, I propose to write (if the same will be acceptable to your readers) a few letters on the subject. I do not intend in so doing to offer, as a rule, any criticism upon what Mr. Swinburne has said, but merely to put on record a few observations of my own for what they are worth. I may resay something Mr. Swinburne has said before me, but if I do it will be only because his and my experience on such points will have been the same.

As I am not writing a series of articles I shall feel no necessity to keep to any particular order in dealing with the subject on hand. I will therefore plunge at once into the midst of affairs:—

Everyone who has had any experience of storing lamps in any quantity must have noticed the very large percentage of them which deteriorate in vacuum. The coil test to which Mr. Swinburne refers is the only practical one which can be employed to assess the value of the vacuum in an exhausted lamp. If we take a "good vacuum" lamp and place one of the terminals of a powerful induction coil in connection with its platinum wires, and the other terminal of the coil a short distance from the bulb, a series of sparks can be made to strike the glass in the same or nearly the same place, and if this action be continued for a certain length of time, dependent on the thickness of the glass and the strength of the discharges, the glass will be punctured and the air will stream in. If the coil discharges are continued whilst the air is entering a most beautiful series of phenomena will present themselves, and all the phases of vacuum discharge, from the total absence of discharge of any kind caused by a vacuum above the point at which any discharge takes place down to simple sparking in a globe full of air, can be studied as they merge one into another during the operation. If care be taken in the experiment, and the punctured hole be made small, *i.e.*, by keeping the discharges at first of minimum force, and by turning the lamp so as to expose a fresh surface to the sparks when the first indication of puncture is seen, the entrance of the air may be prolonged during several minutes, so that ample time will be given for observing the various changes that take place in the discharge.

In almost all the cases I have dealt with in this manner, the bulb of the lamp has been more or less filled after a few minutes' strong discharge with a bluish-grey light before puncturation. The moment of puncturation may be detected by the sudden appearance of a reddish crimson colour, which is, I believe, due to the nitrogen of the air. If we arrest the experiment when the bluish light is shown in the bulb we shall find that in most cases the deterioration of vacuum indicated thereby is permanent, though sometimes the gas causing this colour to appear under the electrification described is partially reabsorbed.

The experience of testing many thousands of lamps for vacuum by the coil teaches us that lamps which have been stored and whose vacua have "gone down" exhibit almost invariably the same bluish-grey light under electrification as is seen when a really perfect vacuum (in an incandescent lamp) is destroyed under heavy discharges of the coil in the manner referred to above.

The old explanation that the lowering of vacuum of well-exhausted lamps arose from minute leaks around the platinum wires, &c., would appear untenable in the light of this experiment, as if *air* leaks into the lamps the characteristic red colour given by nitrogen would be developed on electrification; whereas there is not, according to my experience, one per cent. of lamps suffering from declension of vacuum in which there is any trace of the coloration due to nitrogen.

Under these circumstances one is driven to look elsewhere for the source of the gas (whatever it may be) which by being occluded into the lamp injures its vacuum.

A course of experiments made some years ago led me to the conclusion that this gas comes from the platinum wires used to support the carbon. The following experiment was tried in illustration of the subject.

About 6ft. of platinum wire were rolled up into a helix and the two ends were passed through the ends of an oval-shaped bulb and sealed in, in the ordinary manner. The bulb was then sealed to a pump and exhausted. As the exhausting proceeded the vacuum was tested from time to time by the coil. An unusually large amount of the bluish-grey colour continuously developed itself, making the exhaustion very tedious. When at last the vacuum seemed perfect, a small current was passed for a moment through the platinum wire, when the gas giving the bluish-grey colour with the coil was given off in great abundance. This was again pumped out, and again a second passage of a current through the wire produced a similar result. After a second pumping the platinum wire was heated by a current to dull redness for a few seconds, when the development of the characteristic gas was so great as to quite obscure the interior of the bulb when the electrifications with the coil took place; after again pumping, the wire was made red hot, full red this time, so as to be in danger of sagging against the bulb and breaking it. Owing to this tendency the current had to be put in for only a second or two at a time. The process of pumping and heating was carried on alternately for a long time, until at last it appeared as if all the gas had been given off, and heating the platinum to redness no longer seemed to develop any further deterioration of vacuum. At this point the bulb was sealed off, and the vacuum appeared to be perfect. The next day, however, the vacuum in that bulb was by no means perfect, and within a week it was bad, there being an abundant development of bluish-grey light on the application of the coil test.

In a subsequent experiment I endeavoured to entrap some of the gas given off as above described by the platinum, by sealing a small tube into a bulb, in which the platinum wire experiment above detailed was repeated. When, after careful heating, the gas appeared to be at its maximum, the small tube was sealed off; into this tube wires had been previously sealed to serve as terminals. A powerful discharge was now sent through the small tube, and the spectrum of the luminous discharge was examined. All I can say about this examination is that the result appeared to me very curious; the lines which appeared in the spectrum did not appear to coincide with the lines given for any substance in any text book I could find, and I could only suppose that the gas which is occluded from platinum is so far changed—as regards some of its properties, at least—that it gave—1st, a characteristic bluish-grey light under electrification; and, 2nd, lines in the spectrum not like those given by the same gas before its absorption by the platinum. I had not time to pursue the subject beyond a very few rough experiments, and these conclusions may be wrong.

Whether gas which is occluded from platinum is in any way altered or not by its temporary sojourn in the platinum, it will be abundantly evident to any one who will try the experiments indicated above that the amount of gas given off is comparatively enormous. In several instances I have found that repeated heatings to redness in vacuum, although apparently removing all the gas for the moment, have not ensured the non-appearance of the same sort of gas at a future time. This has so often been observed that one is almost tempted to think that platinum may be porous so as to let gas right through it. The thing looks at the first absurd, but if it be true that water "sweats" through cast iron

Digitized by Google

under pressure—as in a hydraulic ram—I cannot see any inherent impossibility in gas "leaking" through another metal at a lower pressure. The chief difficulty that appears to be involved in such an idea arises from the fact that the effect does not always appear. I believe platinum is commonly "made" by heating a powdery or granular mass to a welding heat, and then treating the same under hammers or rolls. If this be the case, it is easy to imagine, in view of the high temperature needed to melt the metal, that the welding may be in many instances imperfect, and wires drawn from bars so formed may very well have the defects of the original welding reproduced in them, and thus mechanical passages may be afforded for the air or gas. The whole subject is one which I think would well repay careful experiment.—Yours, &c.,

NELSON K. CHERRILL.

FORMULÆ FOR SELF-REGULATING DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question asked by "M," whether the mathematical formulæ given in my book for the conditions necessary for the self-regulation of dynamos are found to be in accord with the practice of manufacturers, is readily answered. The formulæ themselves are in general not; the practical conclusions to which they lead are. For example, the formula No. XXVII. for compounding a dynamo for constant potential is not verified in practice. More series turns are required than that formula indicates, and the reason is simply this: The assumption is frankly made at the outset that the iron in the field-magnet cores is never saturated, and that its magnetism is therefore always proportional to the number of ampere turns exciting it, whereas in actual constant potential machines the series coil is required to come into use most powerfully when the iron cores are well on toward saturation; hence, more series turns are wanted than the theory indicates. But, on the other hand, the practical rule which follows for ascertaining by experiment how many series turns are actually wanted to give self-regulation is constantly used by manufacturers of dynamos. Again, the formulæ for compounding machines, to make them self-regulating for constant currents, are not used, for the additional reason that they would involve an enormous cost for the immense number of turns of wire in the shunt winding. In the expressions for self-regulating motors the formulæ are, however, again good, because in the constant speed motor, running on constant potential mains, the maximum power exerted by the series coils is called forth, not when the field-magnets are most powerfully excited and well saturated, but when they are least excited and furthest from saturation. There will be something said on these points in my forthcoming new edition,—Yours, &c.,

SILVANUS P. THOMPSON.

London, Sept. 20th, 1887.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note in last week's *Electrician* an inquiry as to the practical value of the equations in Silvanus Thompson's "Dynamo Electrical Machinery." The formulæ as mere abstractions are undoubtedly correct, and were it not that the saturation coefficients and the self-induction of the armature are extremely difficult to determine with the ordinary instruments of the workshop, they would be of undoubted use. But, unfortunately, the characteristic of a dynamo or motor does not depend merely upon either the armature or field saturation curves. The characteristic is really the resultant of, firstly, the field saturation; secondly, the armature saturation; thirdly, the depth of the air space; and, fourthly, the external leakage of the lines of force, which depends on the shape and extent of the pole-pieces. Any formula to be of practical value must take into consideration each of these, and we must also assume that they can all be accurately and easily determined by an ordinary electrician with ordinary reading instruments. As an example we may say that using the formula for compounding a dynamo for constant potential we found the series turn to be *one*, but the actual number required was fifteen.—Yours, &c.,

DYNAMO MAKERS.

[CORRESPONDENCE *continued on page 417.*]

OBITUARY NOTICES.

MR. FRANK LAMBERT.

We very much regret to record the death of Mr. Frank Lambert, which took place on Wednesday, the 14th inst. Mr. Lambert was born at Brighton, Sussex, in January, 1836, and was educated at the Grammar School. He served his apprenticeship to Mr. Funnell, watchmaker, of Brighton. The early training in delicate workmanship thus obtained was of the utmost service in his future career. In 1856 he made his first acquaintance with electricity under Mr. E. Orange W. Whitehouse, by whom he was engaged on experiments on the problem of working Atlantic cables. In 1861 he was employed under Messrs. Gisborne and Forde upon the cable made to Government order for a line between Rangoon and Singapore, but which was eventually laid between Malta and Alexandria. Soon after this he joined the staff of Messrs. Sir Charles Bright and Latimer Clark, and was engaged under Mr. Laws in testing the core of the first Persian Gulf cable, when some valuable experiments were made at the Gutta Percha Company's works in Wharf-road on the resistance of gutta percha at various temperatures, from which the tables, now in constant use, were compiled. He served as second electrician on the laying of the Persian Gulf cable in 1863–4.

About the year 1866 Mr. Lambert was appointed by the Indian Government to make a tour in India as instructor to the telegraph staff in electrical matters. This tour occupied him until the end of 1869, and on his way home in 1870 he assisted Mr. Forde during the laying of the cable from Bombay to Aden to Suez. Since that date he has remained in the service of the well known firm of Clark, Forde and Taylor as principal electrician, and has been engaged in the laying of cables in all parts of the world. He was the inventor of several improvements in the keys and other details used in the high-class testing employed for submarine cable engineering. He was also one of the original inventors of "cutting and holding grapnels." He was a member of the Society of Telegraph-Engineers, and a most careful and skilled electrician, respected and liked by all with whom he was ever associated.

CAPTAIN A. H. J. RICHARDSON.

It is with great regret that we have to record the death of Capt. A. H. J. Richardson, late of the Eastern and South African Company's ss. "Great Northern." The late Capt. Richardson caught a fever while on duty on the East Coast of Africa, and was invalided home. He died on Sunday morning, the 18th inst., and his loss is deeply regretted by his numerous friends. Capt. Richardson was born in Saxony. He was forty-six years of age at the time of his death. He joined the Eastern Telegraph Company's service in October, 1870, and worked through the several grades of service to that of commander of the ship. For a brief time in 1874 he was with Capt. Briscoe in the "Hawk," and it was in 1880 that he was given the command of the ss. "Great Northern," stationed at Zanzibar.

It will be seen from these brief notes that he was a man of great experience in his profession, and one who has done good service in cable work. On several occasions it has been our good fortune to meet with Captain Richardson; we have found him always ready to give us the benefit of his experience. He was a general favourite with those with whom he was brought into contact. It may be remembered that he was one of the survivors in the disaster which overtook the "Volta." The remains of the late captain were interred yesterday (Thursday), when a great many of the Eastern Company's officials followed the body to the grave.

MR. O. E. WOODHOUSE.

At the moment of going to press we regret to have to add one more name to our obituary notices this week in the person of Mr. O. E. Woodhouse, senior partner in the firm of Woodhouse and Rawson. Mr. Woodhouse died at Brighton on Wednesday, after an illness of nearly two years' duration.

ELECTRICAL COMMUNICATION WITH LIGHTSHIPS.

Some considerable surprise, not unnaturally, has been occasioned by the Report of the Committee appointed by the Board of Trade to inquire into the desirability of establishing electrical communication from the shore to light-vessels and outlying lighthouses. One passage in that report—which is a very brief one—has especially provoked a good deal of adverse comment. "Without denying," says the Committee, "the very general proposition that all communication with lightships and lighthouses which tend to the saving of life at sea would be desirable, your Committee feel that their decision must evidently depend upon other considerations, very mainly upon that of cost; and bearing that important element in mind we are of opinion that the immediate extension of the system is not desirable." These words, taken by themselves, appear to put the question of expense foremost, and the saving of life virtually nowhere. But in fairness to the Committee it must be confessed that this is not a quite accurate representation of its attitude. After pointing out that the experiment on the "Sunk" Lightship has not been exhaustively tried, the Committee recommend that a final decision should be postponed for eighteen months, and that meanwhile the experimental cable connecting Walton-on-the-Naze with the "Sunk" should be continued. With regard to establishing electrical communication with outlying light houses and islands, Her Majesty's Government is advised to carry through Parliament the Bill for the acquisition by Lloyd's of sites for signal stations.

Although the Report is unusually brief and its conclusion apparently indecisive, the evidence and appendices published with it are voluminous and extremely valuable. A candid perusal of both will afford ample justification for the conclusion arrived at by the Committee, at all events with regard to the particular proposition submitted for its consideration. The special object of the inquiry was that of "facilitating the saving of life at sea," and much of the evidence was directed to this point. But not to this point chiefly, a much larger question very speedily usurping its place, the question, namely, of employing the proposed electrical communication for purposes of signalling ships, transmitting marine telegrams, and generally for commercial objects. Directly the investigation took this turn the subject assumed a quite new aspect, excluding the other, and, as most people will think, more important one, out of sight altogether. For one thing the POSTMASTER GENERAL had to step in to assert his right to give or withhold license for the use of cables landed on British soil intended for the transmission of messages. And although it is perfectly true that the Post Office grants such license with the utmost readiness and on terms which nobody can object to, the assertion of its rights in this relation naturally gave a quite new direction to all the evidence following. It is one thing to lay down cables with the object of signalling for assistance to vessels in distress; it is quite another to employ these cables for signalling messages from ships that wish it to be known they are safe and sound. This latter object is an extremely important one from a commercial point of view; so important, indeed, that not only Lloyd's and certain Steam Line Companies, but even Shipping Newspapers have found it worth their while to establish, with the consent of the POSTMASTER-GENERAL, signalling stations at remote or detached points of the English and Irish coasts, in order to insure early information of the whereabouts of outward and homeward bound ships.

The proposal to use such lightships as the "Sunk" for similar purposes may or may not have been an afterthought, or it may have been in the minds of the promoters all along. In either case the object is quite a legitimate one, and no blame can be attached to them for endeavouring to combine the two, especially as the pecuniary profit likely to be derived from serving the one object would in many instances afford considerable help to achieve the other. In plain words, the costliness of the cables and the expense of working them would be lightened if they could be made to earn something at signalling stations. This, we say, was a perfectly sound and business like suggestion; but it was not exactly what the public were looking forward to. They wanted the lightships connected by telegraph, with the idea of being enabled more quickly to render help to shipwrecked mariners, and are naturally disappointed that the scheme is set aside, or at all events postponed, on the ground, apparently, of expense alone. But this in reality is not the sole ground; and if the promoters are disappointed with the result of the present inquiry they have chiefly themselves to blame. Or perhaps it would be fairer to say that they could not help themselves. The case for saving life broke down at an early stage, and the representatives of the company that laid down the cable to the "Sunk" had to admit that the twelve months' experiment had in that respect not been a great success. No doubt there are situations—off the Norfolk coast, for example—where a series of lightships, connected with each other and with the coast, would be of frequent service in indicating the fact of shipwreck, and its exact position. The evidence of coastguards and lifeboat crews

Digitized by Google

was positive on this point, and we are inclined to agree with it. But, on the other hand, the experts of Trinity House are equally positive that their mission is and ought to be not to save life from wreckage, but to prevent wrecks; and that additional lightships provided with sirens or explosive signals of the newest type are the fittest objects on which to spend public money.

The promoters of the cables do not for a moment attempt to gainsay this proposition; on the contrary, they are as earnest as anybody in their protestations of anxiety to prevent disaster at sea. But they were probably not prepared for the attack made upon their scheme in the form of an objection to its commercial signalling functions. The company's witnesses had urged that in several instances which were cited—notably at Brow Head and at Dover—vessels had been driven into dangerous waters and wrecked through making for signalling points on land. But to this it was retorted that not only would lightships be in danger, of being fouled when approached with a similar object, but that as the situation is always one of danger ships should rather give it a wide berth than be tempted to get near enough to make their signals known. Captain HALPIN admitted that "a great deal of their usefulness as telegraph ships would be lost" unless the lightships were used as signal stations; and indeed to Q. 1,220 ("Your idea would be to make telegraph stations of them?") his answer was "Yes; more in that way than in any other." It is not surprising that the matter was promptly put "in the other way," namely, as to the relative "advantages you would get by telegraphic communication to lightships for reporting" compared with "the risks you would expose the lightship station to." And to this the witness was "not prepared to say how that would be." In a report addressed by Mr. GRAY and Captain NARES to the Permanent Secretary of the Board of Trade, as long ago as June, 1886, this point was treated as one of principle, and it was submitted for serious consideration whether to "encourage ships to approach a lightship in order to use it as a Post Office Telegraph Station, might [not] be to encourage them to approach a danger, and thus prevent the object with which the light-vessel is established."

This is the official view, and it is backed by a long list of light-vessels which have been fouled and damaged more or less during the past six years, when the object has been not to approach but to keep clear of these beacons. The damage done, however, has rarely been serious, and only on two occasions has the light-vessel been sunk. Possibly the list would not have been greatly enlarged had the vessels been used as telegraph stations; and of course none but those situated in positions convenient and safe for passing ships would be specially selected as signalling stations, unless, indeed, experience proved that the greatest safety was insured by multiplying facilities for the interchange of signals. It may also be suspected that the official objection is more on the score of saddling this or that Department with the expense than of the expense itself. The line taken by the Trinity House is that "We do not want the cables for Trade purposes, and, therefore, we do not want to pay for them;" and the Board of Trade follows suit. Fortunately there are other Departments, not Governmental, that do want the cables for Trade purposes, and we venture to think will soon possess them. We venture also to predict that so soon as the telegraphic communication is fairly established by private enterprise, if not by public Departments, with outlying lighthouses, or lightships, the Trinity House and Board of Trade will discover that there is no serious danger attending it, and that it will come in very handy for saving life as an adjunct to the Lifeboat service.

On one point, happily, there is no material difference of opinion. The cable laid by the TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY to the "Sunk" Lightship in March last year has been a complete success. At all points where difficulty was expected it has been easily surmounted; and where interruptions of temporary duration have occurred they have been due to the unexpected—mainly, indeed, to the peculiarly capricious behaviour of this particular ship, which besides being smaller and less buoyant than most vessels of its class, is fitted with an old type of windlass, and has to be frequently "veered" to prevent her light being wholly obscured by every high sea. She turns round twenty times in one direction to once in the other direction, and the consequence is that the telegraph cable gets twisted round the ship's moorings, the unwinding having to be done by manual labour instead of by the ordinary swing of the vessel. The marvel is that, notwithstanding the swivel arrangement with which it is provided, the cable has lasted so long. But, in reality, it remains perfectly sound, and speaking by telephone at all seasons, in storm as in calm, is as easy and trustworthy as on a corresponding length of land line. This cable, nine miles in length, has, in fact, been put to a test more severe than any to which cables of the same pattern would be subjected on the other lightships, none of which are so ill-suited for taking a cable on board as the "Sunk." If no other useful purpose than to establish this fact had been served by the Board of Trade inquiry its Blue Book would be very welcome. But it has done more than this; it has resulted in recommending a further extension of the experiment for eighteen months, and the granting to Lloyd's the sites for signalling stations which Trade purposes, if not Life-saving objects, urgently demand.

THE JABLOCHKOFF PATENT ON DISTRIBUTION BY TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: An unintentional misstatement is made in your review of Mr. Kennedy's papers on "Electrical Distribution." It occurs in the following passage:—

"Chapter III. contains a detailed enumeration of the various patents which have been taken out dealing with systems of distribution in which transformers are employed. The earliest of these is that of M. Jablochkoff, in 1877, who proposed to make use of induction coils with vibrating interruptors for feeding his candles with a higher E.M.F. than that in the mains. We believe that the present owners of this patent contend that the claims cover the whole ground of the use of transformers for distribution, and entitle them to the exclusive use of the method. In November, 1878, a provisional specification (No. 4611) was filed by Messrs. E. Edwards and A. Normandy, in which the use of alternating currents with induction coils was for the first time (?) described. This patent was not proceeded with, but the appearance of the provisional specification having constituted publication, it is difficult to see how any 'master-patent' of still later date can be established. The Gaulard-Gibbs specification is dated 1882, and follows closely on the lines of the 1878 specification above referred to."

Our rights are based on broader grounds than these, and to prevent any misconception that might arise, permit us to draw attention to the following extract from Jablochkoff's patent of 1877, of which we enclose complete copy:—

"Fig. 3 shows the arrangement *in which alternating currents are employed*, such as those produced by most magneto electric machines. This arrangement only differs from the preceding one by the omission of the interruptor and condenser. The coils here shown are similar in construction to those for which the before-mentioned previous Letters Patent

Digitized by Google

have been granted to me. In this case the total system of distribution may consist of a central circuit represented by the series of internal wires of the coils, from which branch out as many distinct conductors as there are bobbins in the circuit. Each lamp is therefore perfectly independent, and may be lit or extinguished separately. The distribution of electricity in a building to be illuminated is in this case similar to the distribution of gas. *As a great number of induction coils can be placed in the circuit, and as a number of lamps may be placed in the circuit of each coil, it will be seen that the electric light is thus capable of very great sub-division.*

"Second ('claim'). The use in apparatus for the production of electric light of induction coils interposed in a primary electric current for generating separate and independent currents to be used for producing electric light in one or more lamps interposed in such secondary circuits, substantially as herein described."

Jablochkoff's claim was complete *before* Edwards and Normandy filed their specification, and constitutes the "master-patent" you imply.

We would not encroach on your space with the correction, but that early developments will require a recognition of our rights in the system generally described as that of "Distribution by means of Secondary Generators."—Yours, &c.,

MANVILLE AND MADGEN,
Managing Directors of the United Electrical Engineering Company (Limited).

Lambeth, September 21st, 1887.

RULES FOR INSTALLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The rumour of a misunderstanding between the Society of Telegraph-Engineers and the fire offices with reference to the Phœnix Fire rules has astonished me a good deal. I had hoped there was no foundation for it; but the letter of your correspondents "Electrical Engineers" leaves little doubt of its truth. I very much regret that this should be the case, the more so at this critical period in the history of electric lighting. The mere whisper of a doubt as to the safety of the electric light, or the sufficiency of the existing fire regulations, may stop orders for lighting theatres and places of public amusement.

I, myself, see no reason for a change. I have used the Phœnix Fire Office rules from their commencement, and have never had any difficulty in complying with them or in getting the work passed by the offices. I mention them in my specifications, and shall continue to do so; indeed, I consider it would be a matter of gain to the electrical profession if the Phœnix rules were generally enforced. Their adoption would determine a standard for specifications, and would prevent the absurd estimates we see daily. But quite apart from the professional aspect, the *risks* are insured by the fire offices, and not by the Society of Telegraph-Engineers, and surely the offices have a right to settle the basis upon which they will accept such risks. Does the society imagine a new set of rules would be generally adopted? *Perhaps a few offices might use them.* I know for a certainty that nearly all the fire offices in this country are with the Phœnix in this matter of rules, and use them. Among so many offices it is quite possible one or two may not care for them, not on account of the "rules" themselves, but from trade rivalry. Are we electrical engineers to play into the hands of the few, and alienate the sympathy of the far greater number who are not only well disposed to the industry but have been our good friends in the past? Such a course of action can only end by throwing the industry into confusion and retarding its progress. I hope, Sir, most sincerely, that the matter will be settled in an amicable way, and that the very efficient set of fire regulations known as the Phœnix rules may be not only allowed to stand but be generally enforced.—Yours, &c,

ANOTHER ELECTRICAL ENGINEER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whether there is any truth in the rumour that we are to have a set of rules from the Telegraph-Engineers I do not know, but certain it is that the Telegraph-Engineers attempted to suppress the Phœnix Fire Office rules, and issue these same rules, under one of their own covers, as coming direct from the Telegraph-Engineers. The Phœnix Fire Office were willing to meet the society in every way, but insisted that due acknowledgment should be given to the fact that they were the "Phœnix" rules. Negotiations were carried on for some time with a view to compromise; but these ultimately fell through, and the result may probably be as your correspondents "Electrical Engineers" suggest, a set of rules from the Telegraph-Engineers. A more unwise proceeding could not be. I feel positive all good firms will stand by Mr. Heaphy. I for one consider his rules excellent. Many is the hour I have spent with him, and never have I had the slightest trouble in complying with them. We know these rules, and are familiar with them, and I venture to say we shall not easily lay them aside.—Yours, &c., J. M. V. MONEY-KENT.

Connaught Mansions, S.W.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read the letter of "Electrical Engineers" in your last edition in reference to the above subject. I am quite astonished to hear that there is any idea of the publication and enforcement of new "rules." Anything more disastrous to the trade it is hardly possible to conceive. At a moment when the talk of the safety of electric lighting as against gas lighting in public places of amusement is paramount in the minds of the public, and when the proprietors of these places of amusement are seriously thinking of replacing gas by electricity, can anything be more likely to shake their faith in electric lighting than to give them any idea that differences of opinion as to security are possible? Even *if* it were true it would be in the highest degree impolitic; but what can we say when there is really no cause whatever to reopen the question?

The Phœnix Fire Office rules composed by Mr. Heaphy are the result of long and practical experience, an experience which it is only possible to attain by every case of accident being brought before one's notice; and Mr. Heaphy stands in the unique position of probably having seen every case in England of fire from electricity. How, then, can a few gentlemen who have not the opportunity of acquiring the knowledge which Mr. Heaphy's position has brought him improve upon Mr. Heaphy's rules? I myself have erected a good many of the most important installations in London and the country, and one or two of them are, I think, amongst the heaviest fire risks the fire offices have. In every case I have followed the Phœnix Office rules, and in no case have I ever had the slightest trouble with the fire offices, in no case have I had trouble in getting the installations passed, and in no case has any electrical fire occurred. Nor can I conceive it possible that a fire could occur if the rules are carried out in their integrity; and I shall continue to adhere to them. I know to a certainty that almost all the large offices have decided to follow the Phœnix Office rules, and it would be interesting to know who those offices are who object to follow them, and what good they have done for electric lighting.—Yours, &c., SAFETY.

THE D'HUMY BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read in your paper an account on my "Water Primary Battery," signed "Iconoclast." It is a pity the space of a valuable paper like yours should accept to print such a false statement, simply to ruin our invention. "Iconoclast" is a perfect ignoramus. When he says that Mr. D'Humy is so ingrossed with his invention that no one has a chance whatever of seeing him, no matter what time of the day or night, or even if one waits all day, it is impossible

Digitized by Google

to get the desired audience. It is so untrue, that I receive about six or seven hundred people a week, and as tired as I am I have never let anybody wait for me three minutes.

It is not with *jeux de mots*, and that *en passant*, "Iconoclast" proves that he is not only a defamator, but a man animated with jealousy.

If you will do me the honour to give me an appointment at my office at the address below, I shall make it my duty to show you a primary battery adapted for central stations and not for private house use.

Whatever may be your opinion on my invention, I forbid Mr. "Iconoclast" to say that I am never at my office. If "Iconoclast" is kind enough to give his real name and address I shall send him an invitation, and he will meet me at my office with people ready to prove how wrong he has been to injure a man in writing such an untruth in your paper.—Yours, &c.,

F. D'HUMY.

The Water Primary Battery Co., Limited,
26, Grays Inn-road, E.C., 17th Sept., 1887.

[We have omitted one or two sentences of this letter which seemed to us merely reiteration of the same statements. The value of the Water Battery is neither increased nor decreased by M. F. D'Humy being found in or out of the office; and in the interests of the investing public we invite a reply to the technical criticism which, after all, may be discovered in "Iconoclast's" letter.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A portion of my last letter was made to appear very ridiculous through a printer's error. It was $Z = 1$; it should, of course, have been $\eta = 1$, the economic coefficient. But possibly Mr. D'Humy has by this time pointed the error out to you himself in a letter of thanks he is sure to publicly accord me in your journal for the points of this battery to which I drew special attention.

Now for the Press notices.

The most important are those of the *Investors' Guardian*, *Iron*, and *The Morning Post*—most important, not only to Mr. D'Humy, whose "inventions" they rightly determine shall not remain in oblivion, but chiefly on account of the weight we must attach to the utterances of such judges of things electric as these journals undoubtedly are.

The *Investors' Guardian* pictures a smiling incredulous gas shareholder paying a visit to Gray's Inn-road. He sees the wonders of that domain; astonishment sways his quivering limbs. He comes out smiling? Oh, dear no; but with a face as long as a pump handle. He is living in a fool's paradise. (To comp'ete the picture we must imagine that his smile again returns. He rushes off to the city, sells out his gas shares, rushes back to Gray's Inn-road. Has he not the *Investors' Guardian* as his guide?)

The same paper assures us that the battery has special and marked features, to which its efficiency (you will recollect, Sir, that $\eta = 1$) is due, and these features rolled into one result in an electromotive couple of great efficiency. Children may light up whole suites of rooms, and may handle the water battery *without danger to its efficiency.* (To think how often I have stumbled over ζ, η, and θ, and in these days children may even play with η without risk.) "It only remains for us (says this authority) "to add that we have made a most thorough and searching investigation of the water battery, and the more we ponder our notes and weigh all the probabilities the more convinced we are that the public have at last secured the light of the future." This seems like half the capital already; even the office boy could not withstand such a straight tip.

Iron assures us that a water battery of twenty cells gives thirty-five volts (? ? ?—the queries are my own, printers' errors run in my head to-day) and forty amperes, and produces 1,000 candle-power incandescent light when divided into 10 candle-power lamps. The lamps, therefore, require only 1·4 watt per candle. [Whose can they be?—ED. *E.*]

The next paragraph must be quoted in full. "By using a different potential of lamp on the same wire, he lights up successively glow lamps varying from 3 candle-power to 1,000 candle-power, and from 1 candle-power from 3 volts to 1,000 candle-power divided from 3 volts to 100 volts. One of the most striking results achieved by Mr. D'Humy is when, by simply turning a switch, he sends the current into a lamp of 100 volts (giving 1,000 candle-power incandescent light), and at the same time and by the same wire another current into a 50 candle-power glow lamp." I quite admit that the effect of putting different volt lamps on the same pair of mains would be very striking. *Iron* also tells us that Mr. D'Humy has a meter that controls *the light consumed per minute*, "a most ingenious arrangement" (without doubt), and *hence* "house-to-house lighting is made perfectly practicable," and winds up by saying that "London must hide its dull, unenlightened head as far as electric lighting is concerned," for only allowing Mr. D'Humy to put down 3,000 lights, whereas abroad he puts them down by the 100,000.

The *Morning Post* endorses in the heartiest fashion every word *Iron* says, especially with reference to the meter, believing that one that controls *the light consumed per minute* renders house-to-house lighting practicable. Quotha: "It is by means of this ingenious arrangement that house-to-house lighting becomes practicable." The "sub-division" of the light is another "feature." "There are thus four important factors—small initial cost, comparative cheapness of maintenance, great durability, and extreme simplicity of manipulation, which latter includes the ingenious division, switch, and meter arrangements."

Barker's Trade and Finance chiefly copies the prospectus. *Money* assures us that nothing but the addition of water to the outer cells is required to maintain the action of the battery.

The *Daily Recorder* is jubilant, and gives us the most remarkable particulars. In describing the exciting elements it ends by saying that "the result is an *electro-motor of great efficiency at an almost nominal cost*," and we are assured that a specimen can be seen working daily at the "Water *Primary* Battery Company's offices."

"The batteries and accumulators giving a current for twenty-five lamps of 10 candle-power can be supplied to the public for an outlay." No doubt you forgot how much! Why didn't you, Mr. *Recorder*, put it down in your notes and "weigh them" like the *Investors' Guardian* did? You are, nevertheless, of opinion that as far as you have seen it is one of the most marked developments of electric power, both for lighting and motor power, which has been produced for some years past, and you say it has been taken up largely by the French Government.

Such, Sir, are the remarks and opinions of the daily journals. Can a boom in the shares of this "Water Primary Battery" be anything but a certainty?—Yours, &c.,

ICONOCLAST.

[We insert these letters of "Iconoclast" more to show the stupidity of penny-a-liners whom he quotes in matters electrical than as directed for or against any primary battery.—ED. *E.*]

GAS IN LIBRARIES.—At the meeting this week of the members of the Library Association, at Birmingham, Mr. C. J. Woodward read a paper in which he explained some experiments he had made as to the influence of gas on bindings. The conclusions he drew were that leather exposed to the foul air in which gas had been burning for 1,077 hours was seriously deteriorated, for the extent to which it would stretch was reduced from 10 per cent. to 5 per cent., while the strain it would bear was reduced in the ratio of 35 to 17, or about two to one. The leather exposed to a temperature of 195deg. F. for 1,000 hours in an atmosphere free from products of gas combustion was also deteriorated, for the extent to which it would stretch before breaking was reduced from 13 per cent. to 9 per cent., while its breaking strain was reduced from 36 to 28. A temperature of 142deg. F. for 1,000 hours had no marked effect upon leather.

COMBINED GAS ENGINE AND DYNAMO PLANT.

We are indebted to Messrs. Crossley Brothers for the accompanying blocks illustrating two different arrangements of combined "Otto" gas engine and Crompton dynamos, which are now on view at the Manchester Exhibition. Those who have seen this plant at work at Manchester will have been struck with the extreme steadiness of running which has now been attained in these engines. By combining the dynamo with the engine it is obvious that not only is space saved, but the cost of foundations is less, and the working strains can be better distributed. Fig. 1 represents a 4 horse-power "Otto" engine, capable of indicating 8 horse-power, and a dynamo capable of filling forty-five to forty-eight 16 candle-power lamps. A large jockey pulley, carried on a very substantial liner, is used to lighten the belt, and for starting purposes it is easy to slack the belt a little and to bring it up to its work gradually.

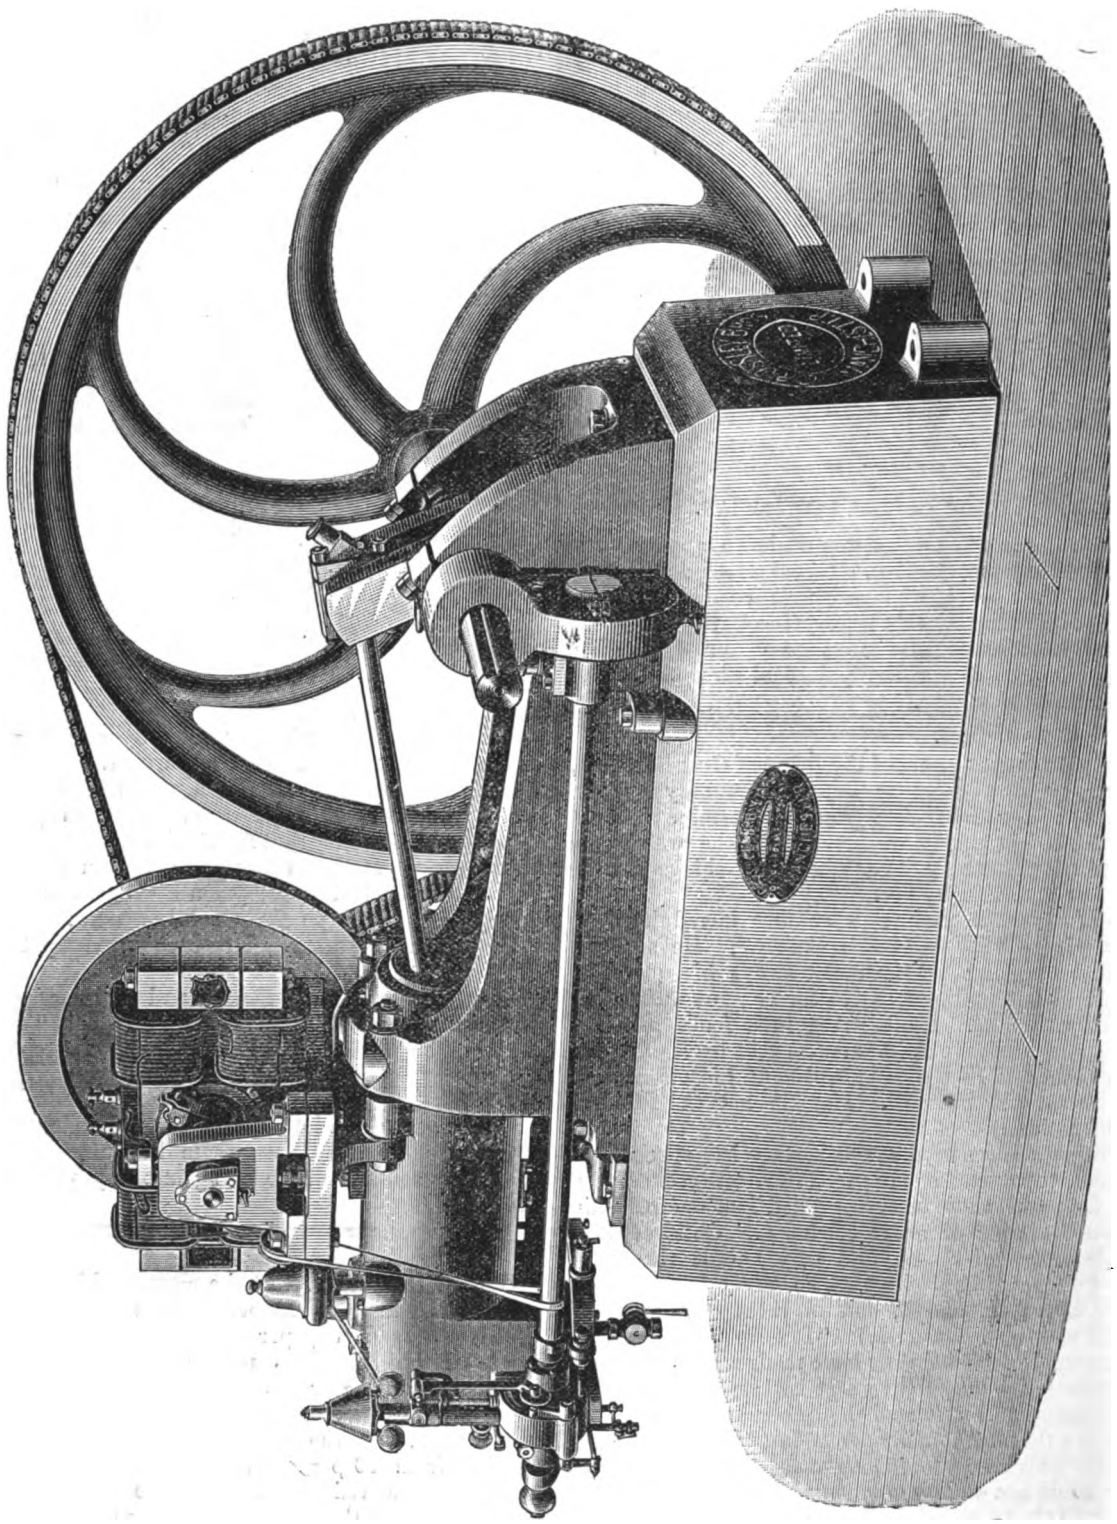

FIG. 1.—Crossley Bros.' Combined Gas Engine and Dynamo.

Fig. 2 is a 1½ horse-power vertical engine indicating 3 horse-power, with dynamo fixed on frame at foot, and is capable of

Digitized by Google

running eighteen 16 candle-power lamps. Other sizes of engines, such as the ½ horse-power indicating 1½ horse-power, are supplied similarly combined with dynamos.

AN ELECTRIC CURRENT METER.*

BY PROF. GEORGE FORBES, F.R.S.

At the present moment the mind of electrical engineers is much directed to the successful means of distributing electricity to a large district from central stations by means of that class of induction apparatus which has received the several names of "secondary generator," "transformer," and "converter." This is the only thoroughly worked-out system available to the engineer for an extensive supply of electricity. Currents of an alternating character (*i.e*, alternately positive and negative in direction, the alternations being at the rate of some hundreds per second of time), and of high tension or pressure, are by this system carried from the engine house, by comparatively thin and cheap wire conductors, to the points of supply. The only difficulty which has been met is in the designing of a suitable meter. There is absolutely no meter available that pretends to be reliable. The very best indicates a totally different result when the same current is passed through it, if the number of alternations of the current (*i.e.*, the speed of the dynamo) be altered.

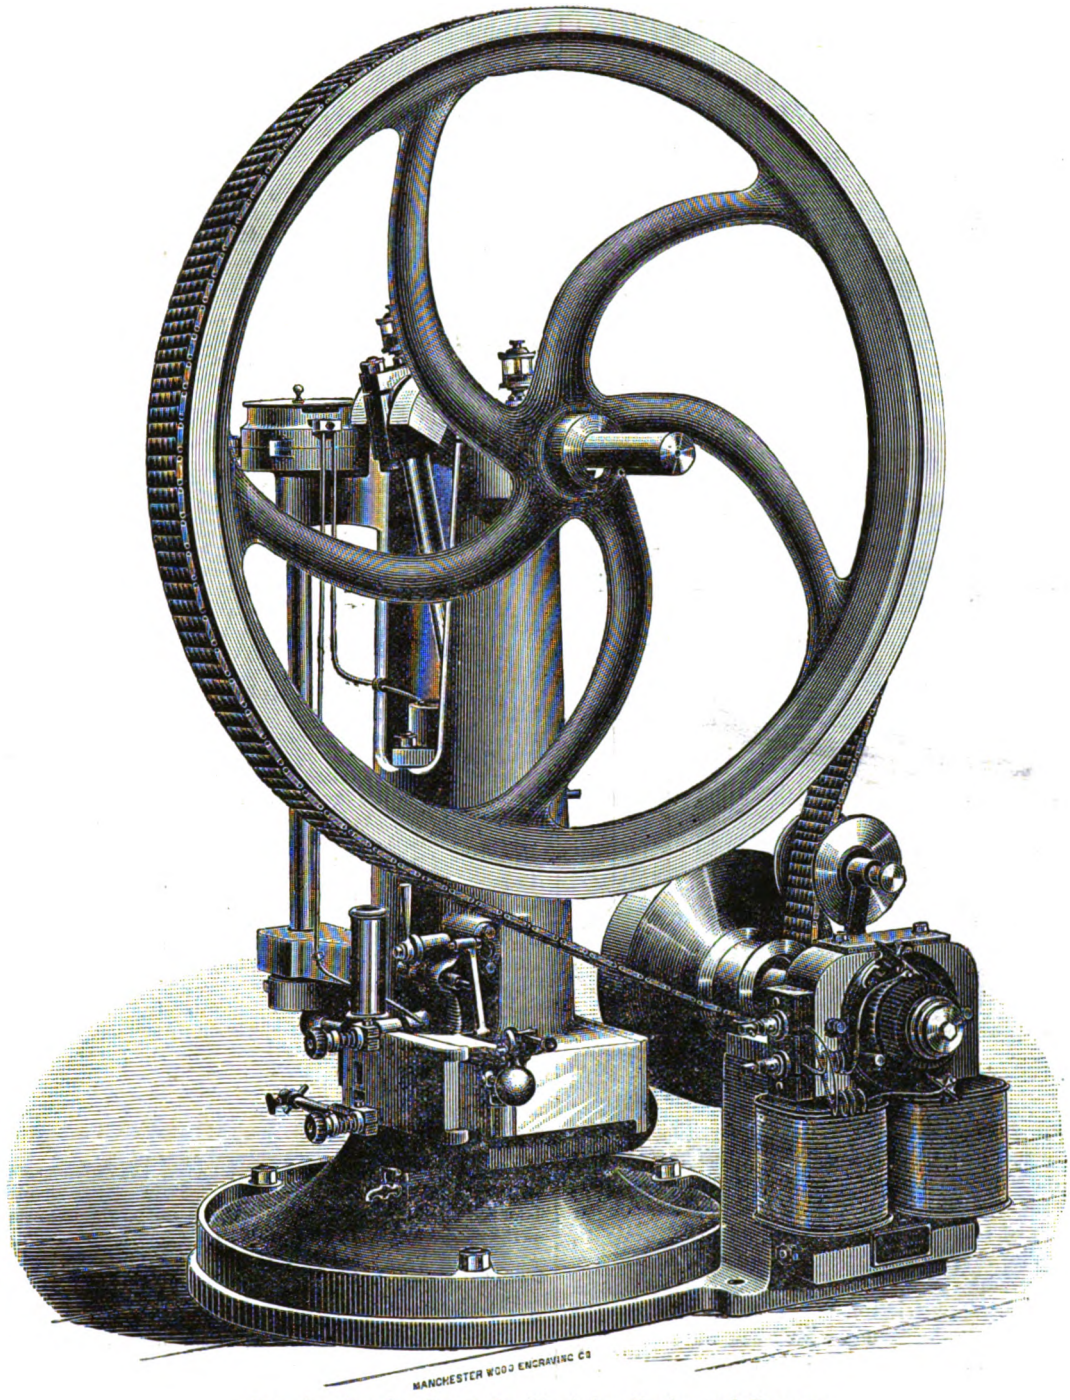

FIG. 2.—Crossley Bros.' Combined Gas Engine and Dynamo.

It was to overcome this source of trouble and to remove the last difficulty from an otherwise perfect system of electric distribution that the author undertook the labour of designing and perfecting the meter here described. Some idea of the work expended in bringing it to its present state of perfection will be gained when it is stated that the trial observations during the development of the instrument number nearly 10,000.

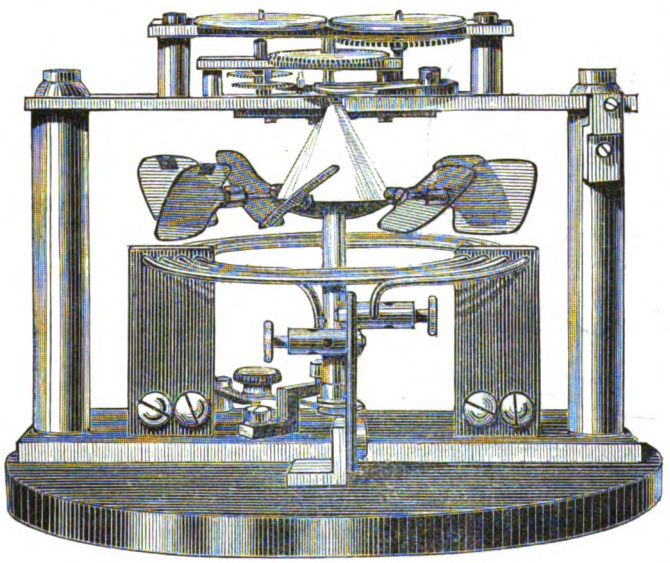
* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

Seeing that the only electrical actions available were those of chemical action, electro-magnetic action, and heat, that the chemical method is incapable of being used with alternate currents, and that all electro magnetic meters must vary in their indications with the rapidity of the alternations, the author was led to base his instrument on the heat developed by an electric current. Such an instrument must be equally applicable to continuous currents and to alternate currents, whatever their rate of alternations. Thus a meter is obtained which is practically perfect and more simple in construction than any of those designed for a more limited range of uses.

The instrument is extremely simple both in principle and in construction. It consists essentially of a flat spiral of iron wire with two terminals. Sometimes these two terminals are united to form one, the other being attached to the middle of the wire. Thus the instrument exhibited may be used as an accurate measure for currents from half an ampere or from one ampere upwards.

Above the conductor a set of vanes is pivoted. This consists of a circular disc of mica with a hole in the centre, in which is fixed a pinion with a concentric ruby cup. Round the circumference of the mica disc eight small cylinders of pith are fixed at equal distances, and eight vanes inclined at 45deg. to the mica discs are attached to the pith cylinders, these vanes being made of the thinnest mica. This set of vanes is supported with the ruby cup resting on a steel point fixed to the base of the instrument. The pinion engages with the first wheel of a train of clockwork actuating the indices, which show upon two dials the number of revolutions made by the vanes.



Prof. Forbes' New Electric Current Meter.

The action of the instrument is very simple. The electric current passing through the iron conductor creates heat, which sets up a convection current in the air, and this causes the vanes to rotate about the vertical axis and drive the clockwork. The number of revolutions indicated on the dials is, through a considerable range of currents, an exact indication of the number of coulombs or ampere-hours which have passed through the conductor. The friction of the ruby cup on the pivot determines the smallest current which can be accurately measured, and the friction of the clockwork is imperceptible.

The following table shows the performance of one of these vanes. The conductor used had a resistance of 0·1 ohm; the first line shows the rate at which the current was flowing through the conductor; the second line gives the ratio of current to speed of rotation, a ratio which ought to be constant :—

Current in amperes	·25	·35	·45	·6	·75	1	2	3	6	12
Ratio of current to speed	76	61·25	50·4	51	50·75	51	51	50·7	51	51·6

When using higher currents the ratio is equally constant.

DISCUSSION.

The CHAIRMAN (Sir F. Bramwell) : The Board of Trade unit is what this meter shows. We have here a most simple form of instrument, which lends itself to the recording of the quantity of electricity used when alternating currents are employed, a difficult problem, which, as Prof. Forbes has told us, his instrument, as simple in construction as a smoke jack, has solved. It really is a smoke jack over electric power.

Sir WM. THOMSON : I have very great pleasure indeed in congratulating Prof. Forbes. Every one who knows anything about electricity understands perfectly that the want of a meter is one of the greatest practical wants in connection with the introduction of central station lighting. I speak feelingly on the subject, for I have tried year after year to produce a meter. There is nothing to which I have given up so much time in endeavouring to make an instrument work as in endeavouring to produce an electric meter, and the Patent Office contains records of some of my attempts. Each one of them has been to some degree capable of giving a result, and the last of them, which I worked at a very great deal till four months ago, promised considerable accuracy, and was perfectly available for either direct or alternate currents. But the difficulty of seeing a way to bring this instrument out, and to make it a practical thing, at a moderate cost, for general use, was so great that I do not feel that I intend to go on with it at all. It is just possible that I might make it succeed as a meter for a larger station. But I am exceedingly glad to see the great success which Prof. Forbes has obtained. I think I may say I am untinged with any feeling of regret at its having been done by another. On the contrary, it is with the most unmixed feelings that I say I am exceedingly glad, and that Prof. Forbes is to be congratulated. With respect to one scientific point raised by what Prof. Forbes has said, we must not be too confident of escaping absolutely in an alternate current meter the effect of different speeds of the engine. Every kind of measurer of alternate currents is affected by different speeds of the engine. In my alternate balance of alternate currents I found it necessary to divide the conductor into thin wires insulated from each other by cotton or silk in order to compel the current to be distributed through the different parts of the conductor equally. In a meter founded upon alteration of temperature a similar effect would hold. If in a thick copper or iron strip, such as would be used by Prof. Forbes with high currents, the self-induction acts so as to sensibly impede the current—if the impedance by self-induction is comparable with the speed of resistance—then Prof. Forbes will be subject to the same difficulty as others. Still I think that in his case the difficulty of practically avoiding effects of self-induction will be much less than in any instrument founded on electro-magnetic force. I am glad to find that Prof. Forbes has with so simple an instrument obtained so perfect a solution of the problem as the numbers he has placed before us prove, and I congratulate him most heartily upon the result.

Prof. PERRY : One has no right to ask an inventor of such a beautiful instrument as this by what means he arrived at the idea embodied in it. I could not have imagined that he could have got this result. The figure certainly shows that it is a beautifully simple instrument, and effects its purpose well. But how any one could arrive at such a method from any theoretical information passes my understanding. The whole action seems to be so complicated. I do not think I should have tried it if the idea had come into my head. I suppose one must miss a tremendous lot of valuable things in this way, because one does not see the theory. I certainly think it is one of the most beautiful things we have had before us for a long time. I speak now as an inventor of a meter which is in considerable practical use, not in this country, unfortunately, but in Germany. That is also a very simple one, but I think that this beats it.

Prof. SILVANUS S. THOMPSON : As another who has tried the invention of a meter, I feel disposed to congratulate Prof. Forbes most heartily on his extremely beautiful and simple solution of the difficulty. I only wish to ask one question, and that is whether this meter, in integrating the various quantities that pass through it, integrates the mean square of the current or the square root of the mean square ?

Mr. A. P. TROTTER : May I ask if the size of the cover has any effect upon the speed of the rotation. Starting with air cold it gets warm with current, and then has to be cooled in order that the rotation may be kept up. I would also ask how much work is absorbed in turning the clockwork, which is the only work it has to do, I suppose.

Mr. R. P. SELLON : I should like to ask Prof. Forbes if he has tried the difference of rotation in the vanes, the difference in the speed of indication for a given current when the air in the chamber is at atmospheric temperature, and again when the meter has been run for some time? as it appears to me that possibly even a small amount of heat given off from the heated wire may, after a certain length of time, raise the temperature of the whole of the air within the chamber.

Mr. F. R. UPTON : At what percentage of the rated capacity of the meter does it start ? That is, after standing for some time. I should also like to ask, if the clockwork which the meter is now turning is without oil and running dry, how much retardation that would cause ?

Mr. LAW asked whether the speed of the meter was affected by the external temperature of the atmosphere.

Prof. BLYTH asked if any irregularity had been observed in the instrument when exposed to all sorts of heat, and whether there was any trace of alteration with the rise and fall of the barometer.

Prof. FORBES, in replying, said that the gentlemen who had asked the questions were really undertaking the whole of the inquiry which he had gone through. It reminded him of the different things that cropped up in the course of the inquiry, and of the way in which they had to be met and the gradual development of the instrument. He would take the remarks of the different speakers in their order. In the first place he wished to tell Sir William Thomson that he sincerely felt the kind way in which Sir William had referred to him, and he was very glad that that gentleman seemed to appreciate the instrument which he submitted to

Digitized by Google

the section. He felt honestly that it was really a good instrument. Sir William spoke about the self-induction and the effect of the unequal distribution that went on in the interior of the wire conductor during the time that an alternating current was passing through it. He (the speaker) confessed that when he got the meter pretty fairly into working order it was with some trepidation that he took it to the alternating current machine and began to make tests. His mind was full of the recollection of the experiments on self-induction which Prof. Hughes had brought before them 18 months before, and which he (the speaker) had followed up in prosecuting the work of Prof. Hughes, and he felt then that probably there would be a great difference in the distribution. He found, however, that an alternating current did not introduce an apparent resistance in the same way, certainly not to the same extent, as a suddenly made and broken current did, and that really in the experiments he had made with the alternating current machine he could not perceive the slightest difference in the effects, whether it was with an alternating or a continuous machine, or at whatever speed the alternating machine was running Prof. Perry could not see any theoretical reason why the instrument should work. That showed that Prof. Perry knew a great deal more about it than the speaker did when he began experimenting. Then it seemed to him perfectly evident that it must work—that it must be suitable for all currents—that the speed would be proportional to the current, owing to the fact that the resistance of air friction was proportional to the square of the velocity, and owing to the fact that the motive power which was created was proportional to the square of the current. They had known for many years that these two circumstances ought to make the velocity of the air current an exact measure of the quantity of electric current that passed through the conductor. To his astonishment it was not so in the first meters that he made. He corrected that gradually, however, and ultimately evolved this difficult instrument—which he thought must be perfect, but which Prof. Perry thought ought not to be perfect. Prof. Perry perhaps was right and he was wrong. Mr. Trotter asked a question about the size of the cover. Undoubtedly the size of the cover made a very great difference. If he enlarged it from one size to another he was able to start with a lower current. The size made a great difference in the minimum current which would start the instrument, for there was a difference of speed with the clockwork on than without it. It was, however, almost imperceptible when it was really in working order, but there was a slight difference in the starting with the clockwork on.

Sir FREDERICK BRAMWELL suggested that "wheelwork" might be a better term than "clockwork."

Prof. FORBES thought it would be, inasmuch as some people might be led into the belief that there was a clock attached to it, which was not the case. With the wheelwork attached it depended very much on the delicacy of the construction of the instrument. He had tried not to construct this instrument too delicately, and the practical instrument which he had been speaking of had no jewelled holes in the wheelwork, and could be made at a pretty moderate cost. The instrument shown was started with one half the current that would be required if he took off the wheelwork, but he had made meters in which it was much less. The principal friction was in the jewelled cup resting on the pivot. The wheelwork friction was very much less. Mr. Sellon asked whether there was any variation in the instrument due to atmospheric temperature and again after it had been running some time. There was none. There was a period in the early stage of the instrument when it had a serious influence on it, but with its final development there was absolutely no difference whether it was running for a long or a short period. For the first five minutes or so it took a little time to get up its full speed, so likewise it took a little time to slow down, but for all practical purposes he thought both these conditions balanced each other. It was a mere trifle in any case. In reply to Mr. Upton, the speaker explained by means of a diagram when the instrument commenced to rotate, and other details. The meters he had spoken of were supposed to be made for thirty lamps, and to indicate one lamp with fair exactness; but it would start with one half of that which was required for one lamp Another gentleman asked whether the external temperature of the atmosphere or any barometrical influence affected it, and whether there was any barometrical correction necessary. In fact, nearly every person had asked him that question. It did not, and that was about the only part of the meter in which practice agreed with theory. It was a very curious thing, but it seemed at first sight as if a higher temperature ought to make a difference; but when they remembered that the motive force was the difference of temperature in the neighbourhood of the conductor and the external air, and not the absolute temperature of the wire, they would see that it did not matter whether the external air was 50deg. or any other figure. As to barometric observations, he had made no tests to see whether there was any difference with variations in the barometer. He had tried the same instrument for long periods of time without finding any difference of the constant, and he was practically certain that the barometrical changes to which they were subject did not introduce changes in the meter. Since he had introduced the spiral conductors he had never had the slightest difficulty.

Sir FREDERICK BRAMWELL said it was needless for him to occupy the time of the section longer, but he would like to say that they must recollect that there were two things needed before the meter became commercially useful. The first was that they should be allowed to use it without any restraint from anybody, and the other was that in using it they should have the means of charging to the consumers the amount of electricity that was supplied to them. Prof. Forbes, he thought, had shown that he had invented a meter most simple in its principle and mode of action, and one that would truly indicate within such limits as were attained in gas meters (and they ought to desire nothing more) the amount of electricity which any person would have to pay for when they had succeeded in getting rid of those unfortunate restrictions which now prevented the supply of electricity from central stations.

FAST-SPEED TELEGRAPHY.*

BY WILLIAM HENRY PREECE, F.R.S.

In this Jubilee year of telegraphy many papers have been read, articles written, and speeches delivered on the progress made during the past 50 years, scientifically, practically, and commercially, but with very few exceptions has any justice been done to the advance made in England in the scientific direction.

Sir William Thomson said, "You have told us how splendidly the land telegraphs are worked; you have pointed out how admirably under the influence of the Government system the application of science to telegraphy has been developed Under Government management within these last seventeen years the applications of science to telegraphy have not stood still, but, on the contrary, have been pushed forward with every possible energy and with the most marvellous success."

I want to describe the evolution of the system of high-speed telegraphy since it left the hands of Wheatstone and Mr. Stroh.

The following table illustrates the progress made:—

Year.	Words per minute.	Speed to Ireland.
1870	80	50·3
1875	100	70
1880	200	150
1885	350	250
Now	600	462

These results have been the consequences of—

1. Greater perfection of apparatus.
2. The elimination of electro-magnetic inertia.
3. The improvement of circuits.
4. Introduction of high-speed repeaters.

Two reasons exist why these great advances have not received notice; they were not patented, and they emanated from Government service. A patent has certainly one great use, it fixes a date and it defines an invention, but it also attracts attention to novelties and improvements, and if the patent be lucrative it incites the immoral to try and do the same thing in another way, which tends to litigation, though often resulting in still further improvements. There is a very ridiculous conception abroad and widely circulated, that commercial enterprise alone is competent to excite inventive skill. I have more than once contested this proposition, but with very little effect, for from the floor of the House of Commons, and from the columns of the press, there is the same cold indifference to the work done in Government departments, and the same cry as tersely put by *Nature*, "The feeling is 'What good can come out of Nazareth?'"

A complete set of automatic instruments consists of

1. The *perforator*, which punches a strip of paper with holes on the principle of the Jacquard loom, so as to regulate the number, order, and rate at which alternate currents of electricity are sent along a wire by

2. The *transmitter*, which is the automatic part of the apparatus, sending along the line those currents which at the distant end are recorded as words in the form of dots and dashes, replacing the slow and uncertain manipulation of the hand.

3. The *receiver*, which is an ink-writer of extreme delicacy and great rapidity, recording the words in the Morse character.

1. The perforator has not been much modified since it left the hands of that accomplished mechanician, Mr. Stroh. Experience has brought out several mechanically weak points, which have been much simplified and strengthened. They have been made to a standard gauge, both as regards the number of perforations per foot,† the strength of springs, and the uniformity of parts, so that interchangability is possible throughout the whole service. The fact that air pressure for working pneumatic tubes exists in many large post offices besides London has led to its application to punching, which

* Paper read before the British Association Meeting, Manchester, September, 1887.

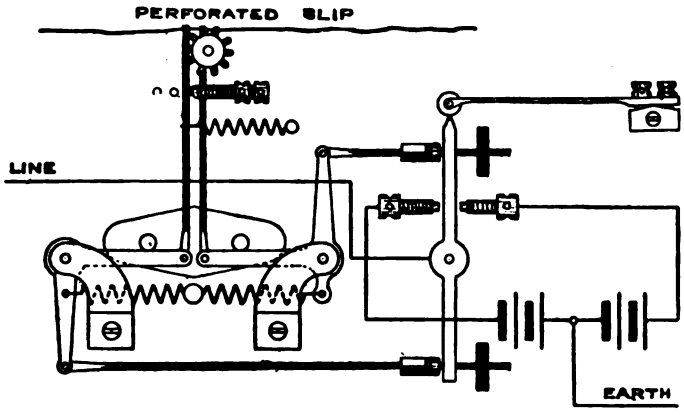
† The standard is 120 centre perforations per foot, or, counting the first and last perforation, 121 centre perforations per foot.

Digitized by Google

is rather a severe mechanical labour, and it has rendered it possible by constructing double-banked perforators to punch eight slips at one time, an invaluable reduction of labour in the transmission of news which has grown to such gigantic proportions that frequently over 1,000,000 words have been sent in one evening from the Central Office in London.

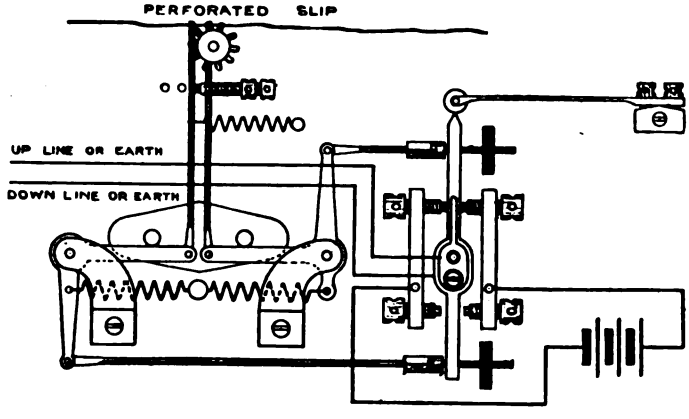
2. The transmitter is an instrument designed to send as many reversals of current per second through the line as the retardation and the electro-magnetic inertia of the circuit will allow. These reversals are rapid alternations of positive and negative currents, the former making dots and called the marking currents, the latter making spaces and called the spacing currents. When the transmitter runs free without any paper to guide it, these currents flow through the line with a regular frequency which is controlled by a beautiful excentric governor invented by Mr. Stroh. This frequency in the present transmitter can be regulated from 14 up to 240 reversals per second, which means 600 words per minute.

FIG: 1.



When unpunched paper is inserted a permanent current goes to line, the motion of the electrical contact that reverses the current is checked or hindered; when the paper is punched then a dot means a complete reversal, a dash means three complete reversals, but the middle one checked by the paper; a space means three complete reversals all checked by the paper. In the earlier form of transmitter the reversal was effected by a commutating arrangement which involved time, and which could not exceed a frequency of 48 or 120 words per minute. It was a very rapid double current key using one battery. In 1883 this plan was revised, a double or divided battery was used, earth being in the centre, the contacts being simple butt contacts.

FIG: 2.

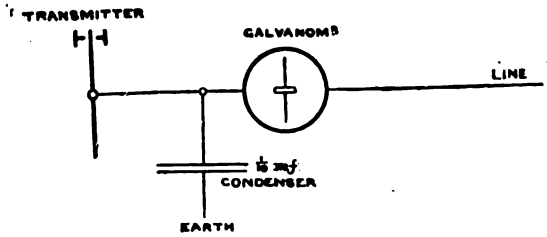


The mechanism was thus very much simplified, and the possible speed of working increased to a frequency of 120 or 300 words per minute. Subsequently, in 1886, the divided battery was rendered unnecessary by a new form of contact of the same character, but requiring only one battery, and the possible frequency was increased to 240, or a working speed of 600 words per minute.

It is evident that with such rapid working the accuracy and perfection of the workmanship must be chronometric in its character. All automatic apparatus is made in the department's own workshops, where mechanicians of the highest skill are employed, where standard gauges are carefully worked up to, and where the most rigid system of inspection is exercised.

One source of trouble has been sparking at the points of contact, which dirties them by disintegrating the metal. Small condensers of $\frac{1}{10}$ microfarad capacity have been applied thus:

FIG: 3.



which considerably modified the evil; but it has been still further reduced by switching out the galvanometer while the transmitter is at work, for sparking is principally due to the presence of electro-magnetic inertia in the apparatus.

3. The receiver has been entirely remodelled both mechanically and electrically. The principal mechanical improvement has been replacing a spring as a motor by a weight in order to secure a more rapid and more uniform rate of running at high speeds, and as a receiver may at one moment have to record at 400 words per minute and the next at 25 when working by hand, it is clear that unless some governor be used the waste of paper would be excessive.

Improved flies have been applied to Stroh's excentric governor so as to make it act with equal efficiency at the present high speeds. Thus, the length of the signals made and the length of paper used per twelve words is practically the same at high and low speeds.

It was thought at one time that the speed of working was limited by the retardation of the line circuit, but a careful inquiry into the phenomena of electro-magnetic inertia (*Journal* of the Society of Telegraph-Engineers, 1877, Vol. V., page 27) led me to the conclusion that the principal source of slowness was in the electro-magnet. It is not possible, owing to this electro-magnetic inertia, to establish *instantaneously* through a circuit containing an electro-magnet a current of the strength due to the electromotive force producing and to the resistance regulating it. The current strength can be brought up only gradually to its proper value.

Every electro-magnet in a telegraph wire becomes an obstruction to the flow of currents, especially when these currents are rapidly intermittent or rapidly reversed. In telegraphs they lower the speed of working, in telephones they blurr the clearness of articulation. It is as though the passage for the flow of electricity were restricted, as the clear way of a water pipe would be choked by the presence of a large stone in the pipe, or the efficiency of a gas pipe would be reduced by its being crushed in by a blow from a hammer. But the peculiarity of the electro-magnet is that the currents themselves cause their own hindrance, and the more frequent they are the greater the throttling or choking action. The action is not dissimilar to that of the throttle valve of a steam engine actuated by a centrifugal governor. Hence, Lord Rayleigh has lately proposed to apply the term "throttling" to this peculiar effect of electro-magnetic inertia. Every electro-magnet has thus a time constant which determines the rate beyond which it cannot work. This time constant can be obtained only by experiment, for it depends on the quality and quantity of iron used, on the form of the core, on the resistance and quality of insulated copper wire, on the number of turns, and on the

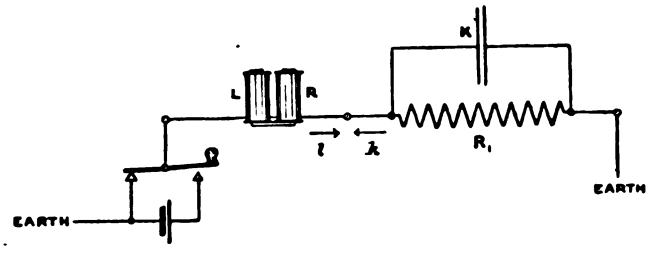
Digitized by Google

way they are wound. The battle with self-induction has been a severe one. Years of labour were devoted to determine the proper conditions to reduce these disturbing elements to their minimum point of hindrance combined with efficiency, until fortunately a means was discovered to entirely eliminate their influence.

Every electro-magnet wound to a resistance R has its own coefficient of self-induction L, which determines the rate at which a current rises or falls, and the time constant is expressed by the ratio $\frac{L}{R}$. It is the time the current takes to rise from zero to its full value.

If the two plates of a condenser of capacity K be shunted by a wire of resistance R_1, then when a current flows the condenser will be charged and the current will consequently gradually rise to its full value, and if the current stops the condenser will discharge and the current will in the same way gradually fall to zero. The time constant of such a condenser is KR_1. This is exactly the same kind of action that takes place in an

FIG. 4.



electro-magnet, and by properly regulating the size of the condenser and the amount of resistance the one can be made to exactly reproduce the former.

Now, if we connect up an electro-magnet and a condenser in the way shown in the following diagram, then, whenever the main current ceases, there is an electromotive force in the magnet due to L, tending to prolong the current in the direction (*l*), while there is an E.M.F. in the condenser K due to the charge tending to do the same thing, but in the opposite direction (*k*). Hence, these two effects oppose and neutralise one another when the resistances R and R_1, the coefficient L, and the capacity K are properly adjusted.

Maxwell has shown that when an electro-magnet and a condenser are balanced in a Wheatstone bridge, $L = R R_1 K$, but in the shunted arrangement (as shown in appendix),

$$L = R_1^2 K.$$

The introduction of the shunted condenser has had the most marvellous effect on the speed of working. It has entirely eliminated any hindrance caused by the electro-magnet, and now the only cause of slow working is the mechanical efficiency of the apparatus and the condition of the circuit. I have pointed out in another paper how copper wire has removed electro-magnetic inertia from the wire, and there remains only the retardation (KR) of the circuit to check speed of working.

Four hundred and fifty words a minute is now obtained with ease on circuits of 200 miles in length, and we have on some circuits reached 600 words per minute; but 450 is more than we can practically cope with, and, therefore, at present the apparatus exceeds in efficiency the capacity of the staff; but this speed rapidly falls off as the retardation of the circuit increases, and while we can work at the highest speed between London and Leeds, we can only get one-fourth of this speed to Glasgow. If, however, we place at Leeds a repeater, which will respond to and relay on these frequent currents, we ought to get the maximum speed to Glasgow, and this is done by the high-speed repeater. The high-speed repeater contains on one board all the electrical functions of two transmitters and two receivers. All causes of hindrance are removed from it, and it works at the highest possible speed. Electrically it is an exceedingly complicated piece of machinery. It owes its efficiency to the perfection of the Post Office standard relay—a relay which has practically no time constant, which responds to exceedingly delicate currents, and which makes perfect electrical contacts—and to the use of condensers.

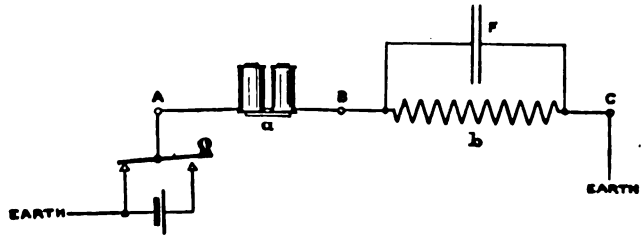
These repeaters are very extensively used. There are special relay offices at Haverfordwest, Nevin, and Anglesey to provide full speed to Ireland. The speed to Ireland in 1870 was 50 words per minute. It is now 462 words—a ninefold advance. Leeds, Manchester, Bristol, and Preston have also special relay rooms. There are 101 repeaters in use. Some circuits, such as those to Aberdeen, have two repeaters in circuit, one at Leeds and the other at Edinburgh. In fact, these high-speed repeaters enable the highest possible speed of working to be obtained to every part of the United Kingdom. They are arranged so as to be used at will either for automatic or for ordinary key apparatus, and either for simple or for duplex working under each class of working.

The introduction of high speed repeaters and the use of shunted condensers have marked epochs in the evolution of telegraphy as eventful as the introduction of duplex working or of the telephone. The various stages of improvement which have been narrated in this paper would each form the subject matter of a patent were it the habit in the Government service to patent. Had the telegraph service been conducted under the severe competition of private enterprise, each form of transmitter and of receiver, the relay, the high-speed repeater, the shunted condenser, and every other improvement would have been patented, and would have been found worthy of substantial reward.

I may add that in bringing about these improvements I have been most ably assisted in the mechanical department by Mr. J. W. Willmot, now the head of our workshops, and in the electrical department by Mr. J. B. Chapman and Mr. A. Eden, both accomplished practical electricians.

APPENDIX.

FIG. 5.



If E be the E.M.F. at any moment taken between A and C, e_1 that between A and B, and e_2 that between B and C, also if *a* be the resistance between A and B, *b* that between B and C, then

$$E : e_1 :: a+b : a$$
$$E : e_2 :: a+b : b$$
$$e_1 = E\frac{a}{a+b},$$
$$e_2 = E\frac{b}{a+b}.$$

The quantity in condenser is

$$Q = e_2 F = EF\frac{b}{a+b},$$

and that discharged from condenser through *a* is

$$q_1 = Q \cdot \frac{b}{a+b} = EF\frac{b^2}{(a+b)^2}.$$

Again, the quantity discharged from the magnet is

$$q_2 = L\frac{E}{a+b} \cdot \frac{1}{a+b} = EL\frac{1}{(a+b)^2}$$

But $q_1 = q_2$

$$EF\frac{b^2}{(a+b)^2} = EL \cdot \frac{1}{(a+b)^2},$$

or

$$F b^2 = L.$$

DISCUSSION.

The CHAIRMAN (Sir Fredk. Bramwell), in opening the discussion, said they would agree with him that it should not be allowed to branch off into a question of the expediency of patent laws, notwithstanding the temptation thrown out by Mr. Preece to do so. He did not say that it was not a subject very much within the competence of Section G, though it was rather more suitable for Section F. But there was a more important scientific side to the subject, which many gentlemen present were quite able to discuss.

Sir WILLIAM THOMSON, who said he had not been present to hear the whole of the paper, congratulated Mr. Preece upon the great success which had been attained under his management in the practical work of telegraphy in the United Kingdom. The figures he had put before them were really of a most remarkable kind. One question with reference to the 600 words a minute which he would like to ask was whether they were all sent in one direction, or in both directions at the same time? He gathered that it was the whole of the work done on the wire in two directions at once. He should be very glad to hear that a speed of 600 words all told in both directions was attainable.

Mr. PREECE: They are all in one direction.

Sir WILLIAM THOMSON: And is the instrument capable of being worked 300 words in one direction and 300 in the other, or only in one direction?

Mr. PREECE: Only in one direction. I have made no reference to duplex working. We have found when working duplex that we can only get half the speed in each direction, so that if we were working at 600 we could only get 300 words in each direction in the minute.

Sir WILLIAM THOMSON said he was thinking of the very beautiful system of Delany which was now in use. But he understood that this was the Wheatstone instrument, and worked in one direction only. They would all, he was sure, be glad to hear one word from Mr. Preece as to whether the Delany system had come into considerable use since he explained it to the section last year.

Mr. PREECE said it would be a great gratification to him if he knew from Sir William Thomson that he had explained the action of the shunted condenser.

Lord RAYLEIGH observed that he was very much interested in Mr. Preece's description of recent progress in the matter of telegraphy. He had really no knowledge of it himself, but there was just one reference that he would like to mention, which he thought many practical telegraphists did not know about, although some scientific electricians did, and that was the paper that appeared some years ago in the *Transactions* of the Edinburgh Society, by Chrystal, who discussed in considerable detail a large variety of arrangements such as that to which Mr. Preece had called their attention and the relations of electro-magnets and resistance condensers, investigating very fully the electrical property involved. No doubt the property used in this particular arrangement was set forth in that paper. One question which it occurred to him to ask Mr. Preece was if he could give them some comparison between the fast-speed rate of telegraphy and the highest rate to be attained by telephony. That would probably convey a definite idea to the minds of many present.

General WEBBER said there was one point which he thought would be very interesting to the meeting to hear from Mr. Preece, and that was the number of individuals that it was necessary to employ at each end of the circuit worked in this way so as to obtain from it its full capacity of 600 words per minute.

Prof. PERRY had nothing to say upon the paper, except to make a reference to the scientific description—the exact mathematical description—of the negative effect which a condenser shunting a resistance had. The condenser acted as a negative self-induction. Mr. Preece's popular description was of considerable value, but the exact mathematical description, very simply put indeed, would be found in a paper by Mr. Sumpner, recently published in the *Journal* of the Society of Telegraph-Engineers and Electricians.

Mr. KAPP asked whether this was the only arrangement of a shunted condenser in use, or whether in some cases Mr. Preece put the plates of the condenser to the terminals of the electro-magnets, which would, he believed, act in the same way, though perhaps it would not do exactly what this arrangement did for telegraphy.

Mr. FAULKNER wished to know whether Mr. Preece had found any difference in speed when using a common electro-magnet and when using a Faulkner altandi magnet.

Mr. TROTTER put a question—which he thought any telegraphist would probably know—how many separate impulses were meant by 600 words a minute? How many letters went to an average word, and about how many impulses to a letter?

Mr. SNELL asked whether the capacity of the condenser required adjustment when working at different rates of speed, or whether the capacity would remain constant, and give sufficiently good results at very different rates of working.

The CHAIRMAN said Mr. Preece would in his reply perhaps touch upon the question put by Sir William Thomson, although it really formed no part of the present paper.

Mr. PREECE: Sir W. Thomson asked a question about duplex working, and I think I answered it at the time, but I will again refer to this point, because it is scientifically an extremely interesting one indeed. We have found—taking the line from London to Dublin, which I have still in my mind—that with a shunted condenser arrangement, and all the latest improvements, the highest speed that it has been possible to get out of the circuit has been 462 words per minute. That shows that the speed is not limited by the apparatus used, but by the circuit. We found that working duplex on the same circuit we got 231 words a minute each way, showing that the speed of 462 words a minute was obtained by utilising every impulse that could be passed through the circuit, and that when we revert from simple to duplex working, we can only utilise the number of reversals or simple currents. Before we reached this limit it was a common thing to find that the sum of the two working duplex was smaller than working single, and that we had not reached the maximum efficiency of our circuit. But now these experiments between London and Dublin have quite satisfied me that at the present moment we are getting out of our circuit all that it is possible to get out of it. But it is a case of "Never say die!" All the work of the last year has shown that there is room for improvement. With reference to what Lord Rayleigh has said, I may say that the sole reason why we have so persistently pegged away at this high-speed working has been the fact that the telephone has been brought out, and that it is possible to get a number of impulses through a circuit infinitely greater than was thought possible before the telephone was introduced. Our eyes have been opened enormously by this beautiful and simple telephone apparatus. I read last year before the Royal Society a paper upon this subject, showing that the law regulating the distance to which we can speak by telephone is precisely similar to that of Sir Wm. Thomson regulating the number of reversals that pass through a current. I am afraid that many of my friends are not quite satisfied that I have made my case very clear or strong, but if I have not done so it has been from my inability to do so. But I am perfectly certain of this, the more they study the subject, the more they work with a high-speed current and telephony, the more surely they will find that there is practically no difference whatever between the current used for telephonic purposes and those used for high-speed telegraphy. Sir William Thomson asked about Delany. The Delany apparatus is another advance in telegraphy in another direction and for another purpose. We ordinarily work a telegraph simple, or simplex—that is, one message in one direction in one time; duplex working means two messages going in opposite directions at the same time; quadruplex means four messages in opposite directions at the same time, so that four messages are passing through a wire simultaneously. But the Delany multiplex has enabled us to send six totally different messages through the same wire at the same time. These messages need not be in reverse directions; all may be in one direction, or one in one and five in another, or they may be mixed up in any combination of six. Sir William Thomson will be glad to hear that we are developing this system very fast indeed. We are I think improving it. We find great difficulty in surmounting the effects of the capacity of our wires, but we are now working from London to Birmingham, from Birmingham to Manchester, from London to Manchester, from London to Leeds, and from Leeds to Carlisle, and this week we are working from London to Glasgow, with repeaters at Leeds. In the last paragraph of my paper I have referred to the assistance I have received in carrying out all these improvements in fast-speed telegraphy from Mr. Wilmott, who is at the head of the workshops; Mr. Chapman, who takes immediate charge of the high-speed telegraph and high-speed repeaters; and especially from Mr. Eden, my assistant here, to whom alone is due the way in which the application of condensers has been so fully carried out. I have only referred here to one use of condensers. They are being used for all kinds of purposes, and the manufacture of condensers is becoming a very important part of my business. Mr. Eden has just returned from Leeds, and he tells me that we have now established between London and Glasgow a Delany multiplex apparatus, with repeaters at Leeds. I hope next year to be able to read a paper upon this subject. Prof. Perry has referred to an extremely able paper by Mr. Sumpner. As a matter of fact, the whole telegraphic world is indebted to Profs. Ayrton and Perry for the way in which they brought the subject of self-induction before the Society of Telegraph-Engineers and Electricians, and their pupil, who developed the subject, showed what admirable means of instruction are to be obtained at the City and Guilds of London Institute if only we send our sons there. Profs. Ayrton and Perry have devised an instrument for measuring this magnetic inertia. I am going to bring the subject before Section A to-morrow, and therefore pass on for the present. Mr. Kapp asked if we had used the condenser as a shunt to the electro-magnet. Of course we have tried that, but, as a matter of fact, if the condenser is used in any other way that shows it acts as a positive, and adds to the retardation of the capacity of the circuit, and has a deterring influence. Mr. Faulkner asks if we have found good results with his magnet. If Mr. Faulkner reads the paper and learns a little more about magnetic inertia he will find that his magnet has a deterring influence rather than a beneficial one on the speed of working. Mr. Trotter asked how many reversals of current there were? Well, it means 240. The frequency is 20 per 50 words, so that if you know the rate at which we are working you get at the frequency at once. When we work at 20 reversals per second it means 50 words per minute.

Sir WILLIAM THOMSON: Ten periods, I understand?

Mr. PREECE: No; 20 periods—20 positive and 20 negative. It is the whole period of the positive and the negative. Mr. Snell asks if we find any variation in the capacity with different speeds. We do not. We find it when working with iron wire, but when working with copper wire at higher speed we find no difference whatever with variation in speed. That is a point I shall refer to to-morrow.

The CHAIRMAN called upon the meeting to accord a vote of thanks to Mr. Preece, and his request was heartily complied with.

STORAGE BATTERIES FOR ELECTRIC LOCOMOTION.*

BY A. RECKENZAUN.

The idea of employing secondary batteries for propelling vehicles is almost contemporaneous with the discovery of this method of storing energy. To Mr. Planté, more than to any other investigator, much of our knowledge in this branch of electrical science is due. He was the first to take advantage of the action of secondary currents in voltaic batteries.

* A paper read at the meeting of the American National Electric Light Association.

Digitized by Google

Planté is a scientist of the first grade, and he is a wonderfully exact experimenter. He examined the whole question of polarisation of electrodes, using all kinds of metal as electrodes, and many different liquids as electrolytes, and during his endless researches he found that the greatest useful effect was produced when dilute sulphuric acid was electrolysed between electrodes of metallic lead.

I need not describe the disappointments which followed the first unfulfilled hopes, nor repeat the criticism that was heaped upon the heads of the early promoters. Those early hopes were untimely and unreasonable. A thousand difficulties had to be overcome—scientific difficulties and manufacturing difficulties. The period of maturity has also been retarded by injudicious treatment, but the ultimate success was inevitable. Great advances have been made within the last few years, and I propose now to offer a few facts and figures relating to the present state of the subject with reference to the application of storage batteries to locomotive purposes. It is not within the province of this paper to discuss all the different inventions of secondary batteries, nor to offer any suggestions with regard to priority, therefore I will confine myself to general statements. I am aware of the good work that was done in the United States by Kirchhof 26 years ago, and of the more recent work of Mr. Brush, of Cleveland, Mr. Julien and others, but I am more particularly acquainted with the recent achievements of the Electrical Accumulator Company, who own the rights of the Electrical Power Storage Company, of London. I have used the batteries of the latter company for propelling electric boats and electric street cars. The first of the boats was the "Electricity," which was launched in September, 1882, and which attained a speed of seven miles an hour for six consecutive hours. Since then a dozen electric boats of various sizes have been fitted up and worked successfully by means of storage batteries and motors of my design. The most important of these were the launch "Volta," and another similar craft, which is used by the Italian Government for torpedo work in the harbour of Spezzia. On the measured mile trial trips the Italian launch gave an average speed of 8·43 miles an hour with and against the tide. The hull of this vessel was built by Messrs. Yarrow and Co., and the motors were manufactured by Messrs. Stephens, Smith and Co., of London. The "Volta," which was entirely fitted by the latter firm, is 37ft. long and 7ft. beam. She draws 2ft. 6in. of water when carrying 40 persons, for whom there is ample sitting accommodation. There are 64 cells in this boat; these are placed as ballast under the floor, and actuate a pair of motors and a screw coupled direct to the armature shaft running at 700 revolutions a minute. We crossed the English Channel with this boat in September of last year, leaving Dover at 10:40 in the morning, arriving at Calais at 2:30 p.m.; stayed about an hour in the French harbour for luncheon, and floated into Dover docks the same evening at 6:30 with full speed. The actual distance traversed without entirely discharging the cells was 54 miles, the current remained constant at 28 amperes until 5 p.m., and it only dropped to 25 amperes at the completion of the double voyage between England and France. Several electric launches are now being constructed in London, and one in New York by the Electrical Accumulator Company.

M. Trouvé exhibited a small boat and a tricycle, both worked by Planté accumulators, at Paris, in 1881.

The first locomotive actuated by storage batteries was used at a bleaching works in France in 1882. During the same year I designed an electric street car for the Storage Company, and this was tried on the lines of the West Metropolitan Tramways in March, 1883. It had accommodation for 46 passengers. This car had many defects, and I reconstructed it entirely, and ran it afterwards in its improved form on the South London Tramways, and also on a private track at Millwall, where it is now in good condition, and I have a similar car in Berlin. M. Philippart exhibited a car in Paris and M. Julien made successful experiments in Brussels, Antwerp and Hamburg. Mr. Elieson is running storage battery locomotives in London. M. Julien has also been experimenting with a car in New York, and I believe one is in course of construction for a line in the city of Boston. Messrs. W. Wharton, jun., and Co. have a storage battery car running at Philadelphia on Spruce and Pine streets, and this energetic firm is now fitting up another car with two trucks, each carrying an independent motor, similar to my European cars.

I have mentioned all these facts in order to show that there is a considerable amount of activity displayed in the matter of storage batteries for street cars, and that continued and substantial progress is being made in each successive case. The prejudices against the application of secondary batteries are being rapidly dispelled, and there are indications everywhere that this method of propulsion will soon take a recognised place among the great transit facilities in the United States. I feel convinced that this country will also in this respect be far ahead of Europe before another year has passed over our heads.

There are several popular, and I may say, serious objections to the employment of storage batteries for propelling street cars. These objections I will now enumerate, and endeavour to show how far they are true, and in what measure they interfere with the economical side of the question.

First objection: The loss of energy, which amounts in practice to 20, and sometimes 30 per cent. Now, every method of storing or transmitting energy involves some waste; but in saying this we need not condemn the system, for after all the term efficiency is only a relative one. For instance, a 10 horse-power steam engine consumes three times as much fuel per horse-power-hour as a 1,000 horse-power engine does, yet this small engine must be, and is regarded as, one of the most economical labour saving appliances known to us. Considered as a heat engine the efficiency of the most economical steam motor is but 10 per cent.—90 per cent. of the available units of heat contained in coal being lost during its transformation into mechanical energy. Thus, if we find that the storage battery does not return more than 70 per cent. of the work expended in charging it, we ought not to condemn it on that account until we have ascertained whether this low efficiency renders the system unfit for any or all commercial purposes. It is needless to go into figures in order to show that, when compared with animal power, this objection drops into insignificance.

The second more formidable objection relates to the weight of storage batteries, and this involves two disadvantages, viz.:—waste of power in propelling the accumulator along with the car, and increased pressure upon the street rails, which are only fitted to carry a maximum of 5 tons distributed over 4 points, so that each wheel of an ordinary car produces a pressure of 1¼ ton upon a point of the rail immediately under it.

The last mentioned objection is easily overcome by distributing the weight of the car with its electrical apparatus over 8 wheels or 2 small trucks, whereby the pressure per unit of section on the rail is reduced to a minimum. With regard to the weight of the storage batteries, relatively to the amount of energy the same are capable of holding and transmitting, I beg to offer a few practical figures. Theoretically, the energy manifested in the separation of one pound of lead from its oxide is equivalent to 360,000 foot-pounds, but these chemical equivalents, though interesting in themselves, give us no tangible idea of the actual capacity of a battery.

Repeated experiments have shown me that the capacity of a secondary battery cell varies with the rate at which it is charged and discharged. For instance, a cell such as we use on street cars gave a useful capacity of 137·3 ampere hours when discharged as the average rate of 45·76 amperes, and this same cell yielded 156·38 ampere hours when worked at the rate of 22·34 amperes. At the commencement of the discharge the E.M.F. of the battery was 2·1 volts, and this was allowed to drop to 1·87 volt when the experiment was concluded. The entire active material contained in the plates of one cell weighed 11·5lbs., therefore the energy given off per pound of active substance at the above high rate of discharge was 62·225 foot-pounds, and when discharging at the lower rate of 22·34 amperes the available useful energy was 72·313 foot-pounds, or nearly 2·2 electrical horse-power per pound of active matter. But this active substance has to be supported, and the strength or weight of the support has to be made sufficiently great to give the plate a definite strength and durability. The support of the plates inclusive of the terminals above referred to weighs more than the active material, which consists of peroxide of lead and spongy lead; so that the plates of one cell weigh actually 26·5 pounds. Add to this the weight of the receptacle and acid, and you get a total of about 41 pounds per cell when in working order. Seventy of these cells will propel an ordinary street car for four hours and a-half, while consuming the stored energy at the rate of 30 amperes, or over 5·6 electrical horse-power. The whole set of seventy cells weighs 2,876lbs., which is barely one-fifth of the entire weight of the car when it carries forty adult passengers, therefore the energy wasted in propelling the accumulator along with a car does not amount to more than 20 per cent. of the total power, and this we can easily afford to lose so long as animal power is our only competitor. From numerous and exhaustive tests with accumulators on cars in this country and abroad, I have come to the conclusion that the motive power for hauling a full-sized street car for fifteen hours a day does not exceed $1.75, and this includes fuel, water, oil, attendance, and repairs to engine, boiler, and dynamo. We have thus an immense margin left between the cost of electric traction and horse traction; and the last objection, that relating to the depreciation of the battery plates, can be most liberally met, and yet leave ample profits over the old method of propulsion by means of animals.

The advantages of storage battery street cars for city traffic are self evident, so that I need not trouble you with further details in this respect, but I would beg those who take an interest in the progress of the electric locomotive to give this subject all the consideration it deserves, and I would assure them that the system which I have advocated in this brief but very incomplete sketch is worthy of an extended trial, and ready for the purposes set forth. There is no reason why those connected with electric lighting interests in the various cities and towns should not give the matter their special attention, as they are the best informed on electrical engineering, and already have a local control of the supply of current needed for charging.

DIRECT SPANISH TELEGRAPH COMPANY.

Report and accounts of the Directors for the half year ended 30th June, 1887, to be presented at the general meeting of shareholders, to be held at Winchester House, Old Broad-street, E.C., on Friday, the 30th inst., at twelve o'clock:—

The accounts for the half year show, after providing for debenture interest and a charge for renewal referred to in paragraph 5, a balance to the credit of profit and loss of £4,649. 10s. 3d. The traffic receipts show an increase of £366. 19s. 9d. as compared with the corresponding half year of 1886, when a higher rate of tariff existed than at present. The balance-sheet shows for the first time the capital as reduced in accordance with the order of the Court. Both the Company's cables and the land lines in connection with these have continued in good working order throughout the half year. In the month of February a favourable opportunity occurred of renewing and altering the position of the shore-end of the cable at Marseilles, and of leading a new subterranean land line from the cable landing along a greatly improved route. This renewal was effected by the Eastern Telegraph Company at a very small cost while that company was renewing their own shore ends and land lines. The cost of this renewal has been charged to revenue. The Directors have, in accordance with the policy announced when the reduction of capital was agreed to by the shareholders, put £2,500 of the balance of profit and loss to the reserve fund,

Digitized by Google

which now amounts to £5,899. 8s. 3d., and there will then remain £2,149. 10s. 3d. available for dividends. The Directors recommend the payment of the dividend of 10 per cent. on the preference shares, and a dividend at the rate of 2½ per cent. on the ordinary shares, free of income tax, and to carry forward £2. 19s. 3d. to next account.

CITY NOTES, &c.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended 15th September are £1,989, as compared with £1,864 in the corresponding period of 1886.

AN ADDRESS.—Messrs. Mix and Genest, of Berlin, whose microphone was recently described in our columns, ask us to state that their address is Neuenburger Strasse 14A, Berlin.

NOTES.

CABLE REPAIRED.—The cable between Trinidad and Demerara, interrupted in the early part of this month, is now restored.

THE LIVERPOOL EXHIBITION.—The people of Liverpool are so dissatisfied with what they consider the emptiness of the Exhibition that they have christened it "The Spaceries."

A LONG CIRCUIT.—It is said that the longest regular land circuit in the world belongs to the Western Union Company, and runs from New York to Galveston, Texas, a distance of about 2,000 miles.

CITY AND GUILDS OF LONDON INSTITUTE.—We notice that Prof. Ayrton is to give a course of lectures on Electrical Technology at the Central Institution. These lectures will be given on Mondays and Thursdays, from 10 to 12, and commence on 6th October.

SHORTHAND.—In his address to the International Shorthand Congress, the Earl of Rosebery referred to the pressure of the times upon every class of civilised humanity, and stated that the telegraph, the telephone, and the postal card, in addition to shorthand, are nothing but the signals of distress of an overstrained civilisation.

IRELAND.—Besides ripping up the railroad to stop the passage of a train conveying the constabulary to a disturbed district last Tuesday, the insurgents broke down the telegraph wires. We call the offenders insurgents because these are operations of a kind which usually denote the beginning of warfare, whether civil or international.

IN THE FUTURE.—The *Financial News* says an electric car company will shortly be launched with the object of introducing electricity as a motive power on street cars and tramways. The experiments so far made are reported to have met with a fair measure of success, and if the investing public respond there is to be a new sort of electric boom.

TRAVELLING POST OFFICES.—From the Postmaster-General's Annual Report we learn that electric bells in the Railway Travelling Post Offices for the purpose of indicating when the mail bag exchanging apparatus is in working position have been introduced with great advantage, and that the system will shortly be extended to all the travelling post offices.

TELEPHONY FROM BERLIN TO HAMBURG.—The German Administration of Telegraphs, finding that the telephonic line between Berlin and Hamburg suffers from too much traffic, has reduced the duration of each conversation from five to three minutes, the price remaining the same. This measure has called forth some very lively remarks from the public who were accustomed to use this telephonic communication.

CHAMBERS OF COMMERCE.—At the meeting of the association just concluded, Mr. Dunlop, on behalf of the executive council, moved, and Mr. Murray, of London, seconded, that in any renewal of the concessions to the Submarine Telegraph Company it is desirable that the charges should be revised, and that representations be made to Her Majesty's Government to that effect. This motion was unanimously carried without discussion.

TELEPHONY AT SOUTHAMPTON.—The telephone company in this town have now 70 subscribers on their exchange service, a large number considering the short time the service has been established, and a convincing proof of the value of the system to men of business. The company are about to open an exchange service at Winchester, in connection with the Southampton district, of which Mr. P. Fitzsimons is the superintendent.

CHINA.—American advices state that the Mitkiewicz-Barker Chinese banking, railway and telephone concession has been ratified by the Chinese Minister at Washington. It is understood that $25,000,000 is the amount of capital to be invested, and report has it that Mr. Wharton Barker and some of his associates will go immediately to China to organise a national bank and lay out plans for the first railroad, which will probably be a strategical one for the transport of troops.

THE INDIA TELEGRAPH SERVICE.—A Reuter's telegram, dated Simla, September 26th, states:—"A dispatch has been received from the Secretary of State for India in reference to the block in promotion in the Telegraph Department. It directs that extra pensions are to be offered to induce officers to retire earlier than is allowed by the present regulations, and rearranges the graded list of officers with a view to give immediate relief. The dispatch states that no further concessions will be granted."

ELECTRIC LIGHT ON RUSSIAN RAILWAYS.—The Russian Minister of Ways of Communication has, says a contemporary, appointed a special commission to select the best system of electric lighting for railway carriages. This is the result of a decision recently arrived at to render the adoption of the electric light compulsory upon the principal railway companies for all passenger trains. The experiments will be conducted on the Nicolaieff Railway, and are not expected to last more than a month.

TELEPHONE MONOPOLY.—Do the people who write to the political papers ofttimes know what they are writing about? Those who declaim against telephonic monopoly in a given district will perhaps enlighten us as to the effect of two or three companies working in the district. We can see how bad such a competitive system would be, and our difficulty is to find out how it would benefit anyone.

LODESTONE.—Although almost every schoolboy knows Pliny's account of the discovery of glass, we do not remember to have seen in any electrical paper or treatise any mention of his reference to the lodestone in the history of this discovery. Yet Pliny, after describing the accidental discovery by the merchants, goes on to say that afterwards (as man's wit is very inventive) men were not content to mix nitre with the sand, but began to put the lodestone among the sand, thinking it would draw the liquid glass unto it, just as it drew iron.

BIRTHPLACE OF MORSE.—The house in which Prof. Morse the inventor of telegraphy, was born is still standing in Charlestown, Mass. It is on the corner of Main-street and Hathon-square, and is occupied by two families. On the street floor are two stores, one occupied as a grocery and the other as a shoe store. This house was one of the two that remained unharmed when Charlestown was destroyed by fire by the British in 1775. Morse was an artist of some merit, and on the walls of several of the rooms are to be seen sketches in oil from his brush.

THE VAN RYSSELBERGHE SYSTEM.—According to the proceedings of the Belgian Society of Electricians, the Van Ryssel-berghe system is applied to over 9,000 miles of line, of which nearly 4,500 miles are in Belgium, about 2,500 miles in France, about 600 miles in Germany, and the rest in Austria, Bavaria, Denmark, Spain, Holland, Switzerland, and Wurtem-

Digitized by Google

burg. The system is in process, or is projected, some 3,700 miles in addition to the above, some of these extensions being in Turkey, Russia, Roumania, Portugal, and Italy. It will be recollected that this system permits of utilising the same wires for telegraphic and telephonic communication.

THE ELECTRIC LIGHT AND MOBILISATION.—It is interesting to learn that in the recent French mobilisation experiment the electric light industry was called upon to furnish its contingent. The work was carried out by MM. Sautter, Lemonnier and Co., who had to supply, at very short notice, the necessary materials to light the principal points of embarking and disembarking the cavalry—two at Toulouse and one at Carcassonne. At each station there was a dynamo giving 16 amperes current at 600 volts feeding a new arc lamp of 150 carcels. The dynamo was mounted upon the same truck as a portable engine, which was used to drive it, so that the whole of the apparatus could be easily removed.

MEXICO.—When we come to recognise that Mexico possesses more than 20,000 miles of telegraphic lines, besides the telephonic, it will be seen that a large amount of material is required for the filling up of the lines and offices. In providing such materials England seems to have a very small share, the greater quantity being obtained from the United States. The apparatus used is simple and duplex Morse. The line wire is of galvanised iron of 4mm. diameter. The insulators are those of the Chicago Insulating Company. The poles are of Eucalyptus wood, and seem to be about the only part of the apparatus provided by Mexico. Similarly with the telephonic apparatus, almost the whole of which has been provided from America.

BOOKS RECEIVED.—The fourth edition of *A Handbook of Electrical Testing*, by H. R. Kempe, is published by Messrs. Spon. Our opinion of this book has been often given. It is one of those few works that cannot be praised too highly. By far—in fact, it cannot be said to have a competitor—the best book on the subject of testing, it has been carefully revised and added to till it is almost impossible to conceive of further improvement. No electrician worthy the name can do without this work.—We have received also a copy of the new edition of Dr. Gore's *Theory and Practice of Electro-Deposition*. This work was, we believe, originally written for the "Circle of the Sciences," and according to the preface the necessary alterations and additions have been made in this edition to bring it up to date.

WESTERN COUNTIES TELEPHONE COMPANY.—The directors have resolved to allow the subscribers to their exchange systems and the public in Bristol, Bath, Gloucester, Newport, Cardiff, Pontypridd, Swansea, Llanelly, Landore, Morrison, Neath, and Briton Ferry to communicate with each other upon payment of certain small amounts varying from 6d. to 1s., and in order to convenience the subscribers they have decided to allow them to speak direct from their own offices, the account to be rendered monthly. Of course it is almost impossible to say how such an experiment as this will answer, but, as we have often argued, the success of experiments of this character will show how rapidly the telephone will compete with the telegraph. The advantages altogether are in favour of the telephone, inasmuch as not twenty words but a tolerably long sentence and a reply can in a very short period be transmitted and received.

LIGHTNING CONDUCTORS.—The *Electrotechnischer Anzeiger* describes a method patented by Messrs. Hoyer and Glahn (of Schönebeck, on the Elbe), who use an insulated copper wire introduced into the conducting apparatus and wound round an iron core. Over the core is suspended a magnetised steel plate. The latter communicates with a registering appliance, by which its movements are recorded. When a current of electricity passes through the conductor the iron core becomes magnetised and attracts the corresponding pole of the plate. After the cessation of the magnetic action the small plate will remain in its position. From the position of the indicator it is possible to determine whether lightning has passed through the conductor. In order to restore the apparatus to its original condition the indicator is turned back, the plate liberated and again suspended. It is stated that several hundreds of these appliances are already in use.

THE FIRST LIGHTNING CONDUCTOR.—If we are to believe an Austrian paper, says *La Lumière Electrique*, the first lightning conductor was not constructed by Franklin, but by a monk of Seuftenberg, in Bohemia, named Prohop Diwisch, who installed an apparatus the 15th of June, 1754, in the garden of the curate of Prenditz (Moravia). The apparatus was composed of a pole surmounted by an iron rod supporting twelve curved up branches, and terminating in as many metallic boxes, filled with iron ore and closed by a boxwood cover, traversed by 27 sharp iron points, which plunged at their base in the ore. All the system was united to the earth by a large chain. The enemies of Diwisch, jealous of his success at the court of Vienna, excited the peasants of the locality against him, and under the pretext that his lightning rod was the cause of the great drought, they made him take down the erection which he had utilised for six years.

OVERHEAD TELEPHONE WIRES AT DORCHESTER.—A correspondence has, we understand, been going on for some weeks past between the Town Council of Dorchester and the Secretary of the Western Counties and South Wales Telephone Company, who have erected a telephone wire across the Cornhill of that town, and declined to remove it, notwithstanding the protests and threats of the local council. The contention of the latter appears to be that they possess rights not only over the streets and buildings but over anything that may be carried across and above them. On the other hand, the company very naturally rely upon the ruling in the well-known Wandsworth case, and are averse even to admit the right of the council to require their sanction for any extension of the telephone company's business by overhead wires across the thoroughfares. Legal proceedings are threatened by the Town Council, the company meanwhile expressing their intention of erecting fresh wires wherever their business requires them.

PERSONAL.—A large number of telegraphists and others assembled on Friday last at the Nag's Head, Cloth Market, Newcastle, to bid farewell to two of their colleagues, Mr. R. W. Weightman and Mr. J. Younghusband, who are leaving to accept appointments under Government at Pietermaritzburg. Mr. M'Keone, in a short speech, presented each of these gentlemen, on behalf of the clerks in the Newcastle telegraph offices, with a large portmanteau, Mr. Weightman suitably responding. A letter was read from Mr. Younghusband regretting that, owing to his being desirous to spend the few remaining days in this country at his home in Keswick, he was unable to be present, but thanking his friends for the gift they had so kindly made him. Several other gentlemen spoke in the highest terms of Messrs. Weightman and Younghusband, after which songs were efficiently rendered by Messrs. H. Dowey, M. Brown, A. S. Lisle, F. W. Holmes, N. F. Clutterbuck, H. Kemp, Liddell, Taylor, and Weightman.

ELECTRIC LIGHTING TARIFF IN MILAN.—At Milan there are now two distinct tariffs in operation, one based partially on a fixed annual charge, and the other upon the actual consumption. In the first case the rates are as follows :—

For 1	ampere	45	lires per annum	+5·5	centimes per hour of supply.			
,, 0·75	,,	35	,,	,,	+4·0	,,	,,	,,
,, 0·5	,,	22·5	,,	,,	+2·66	,,	,,	,,

The second tariff, in centimes, is as follows :—

	Below 41 hrs.	41 to 80 hrs.	81 to 100 hrs.	101 to 125 hrs.	126 to 150 hrs.	Above 150 hrs.
For 1 ampere	12	11	10	9	8	7·5
,, 0·75 ,,	9	8·25	7·5	6·75	6	3·6
,, 0·5 ,,	6	5·5	5	4·5	4	3·75

The meters are rented on the following terms :—

6 lires per annum.....for 50 lamps.
9 ,, ,, ... ,, 50 to 100 lamps.
12 ,, ,, ...above 100 lamps.

The company replaces the lamps burnt out at their own expense. Many of the above prices have no exact equivalent in English money, but are fractions of a penny.

ANOTHER ELECTRIC BOAT.—By the command of the Minister of Marine a series of experiments has been carried out at Havre with a new electric boat, designed for use in the French Navy. The boat under experiment was constructed by the Forges et Chantiers de la Méditerranée. The electric motor was from the design of M. Krebs, developed with a velocity of 850 revolutions, about 12 horse-power, driving a screw of 0·55 millimetre in diameter, about 280 revolutions per minute. The electric current is furnished to the motor by a battery of 132 accumulators upon the system of MM. Commelin and Desmazures, presenting, it is said, some decided advantages ; but of this it is impossible to speak unless we had a complete knowledge of the invention. The weight of the accumulators was about two tons. They furnish from eighty-seven to eighty-nine amperes, with a difference of potential from 100 to 104 volts. The constructor of the boat guaranteed a velocity of six knots for three hours, with ten horse-power during the experiment. The launch gave 6½ knots during five hours, developing twelve horse power.

CURIOUS EFFECTS OF LIGHTNING.—Our American contemporary *The Scientific American* reports that "The steamship 'Anchoria' of the Anchor line, which lately arrived in New York, met a tornado 180 miles from Sandy Hook. The wind came on from the north-east, and in a short time there was a tremenduous sea running. The rain came down in such floods that the crew were scarcely able to stand upon deck. The lightning poured in streams of a minute's duration from the clouds to the water, while globes of blue flame played up and down the rigging and danced along the yards, and leaped from the masts incessantly, terrifying passengers and seamen alike. For about two hours the wind blew at eighty miles an hour. Neither lookout nor pilot could see beyond the ship's rail, because of the solid sheets of rain and flying clouds of spray in which the ship seemed to be walled up as by a fog. The engines were run dead slow, and the ship lay to, head to the gale. At the end of two hours the gale broke, and pleasant weather soon followed. No damage was done by either wind or electricity. The steamship 'Glenartney,' from Shanghai, was in the same storm, and had well-defined tufts of electric fire on each masthead."

TELEPHONE EXTENSIONS IN SOUTH YORKSHIRE.—The Sheffield Telephone Exchange Company are busily engaged in making important extensions and developments of their system. Sheffield and Rotherham have been connected by telephone for many years, and subscribers in Rotherham have been in direct communication with the Sheffield Exchange by separate wires. The majority of the original Rotherham subscribers prefer to continue these direct connections, but a demand has arisen for a cheap local service which will at the same time provide communication with the Sheffield subscribers, and a central office has now been opened in Rotherham. New subscribers are being quickly attached, and the communication with Sheffield is provided by means of trunk wires. The wires are also being energetically pushed forward to Barnsley, and they will connect on their way the towns of Swinton, Wath, Kilnhurst, Mexbro', and Wombwell, thus uniting the large and important coalfields of South Yorkshire with the leading towns of Sheffield, Rotherham, and Barnsley. The local authorities over the entire route have cheerfully granted facilities for the erection of poles and wires, and have been prompt to recognise the commercial importance of the facilities that will shortly be at their disposal.

AMERICAN EXAMPLE.—Undoubtedly the meetings of the Electric Light Convention in America fulfil an object which it seems to us we in England should strive after. We have nothing of a similar character connected with electrical engineering, and certainly an attempt should be made to bring practical men together occasionally to talk over the practice of their profession. The scientific value of the papers read by our friends on the other side may sometimes be represented by a negative quantity, but the utility of the papers and the meeting is that, from beginning to end, the aim is to further "business" by discussing practical questions ; and when practical men will discuss their successes and their failures, good must assuredly ensue. What do our English practical men say ? Shall we take the work in hand, initiate a working committee, call a meeting and test the scheme, or let it drop ? How would the following names do for an executive committee :—Mr. Crompton, Mr. Parker, Mr. Garcke, Major Flood-Page, Mr. Sellon, Mr. Wharton, Mr. Statter, Mr. Fricker, Mr. Fletcher, Mr. Bennett, Mr. Walker, Mr. Kay-Gray, Mr. A. Siemens ? Mr. Fricker would no doubt act as secretary. Other names might be suggested, but these, we think, are fairly representative. We suggest that all those favourable to the idea should signify the same in the usual manner, viz., by writing and saying so.

A STRATAGEM.—According to the *Electrical Review* of New York, when the electric telegraph was first introduced into Chili a stratagem was resorted to in order to guard the posts and wires against damage on the part of the Araucanian Indians and maintain the connection between the strongholds on the frontier. There were at the time between forty and fifty captive Indians in the Chilian camp. General Pinto called them together, and, pointing to the telegraph wires, he said—"Do you see those wires ?" "Yes, General." "Very good ; I want you to remember not to go near nor touch them, for if you do your hands will be held, and you will be unable to get away." The Indians smiled incredulously. Then the General made them each in succession take hold of the wires at both ends of an electric battery in full operation. After which he exclaimed, "I command you to let go the wire !" "I can't; my hands are benumbed," said the Indian. The battery was then stopped, and the man released. Not long afterwards the General restored them to liberty, giving them strict injunctions to keep the secret, and not to betray it to their countrymen on any account. This had the desired effect, for, as might be expected, the experiment was related "in the strictest confidence" to every man of the tribe, and the telegraph has ever since remained unmolested.

EARLY EXPERIMENTS.—Berzelius relates that Hansteen and Maschmann placed a solution of silver in a syphon-shaped tube that the silver might be reduced by metallic mercury, and they always found that when the two legs of the tube stood in the plane of the magnetic meridian, the silver in the northern leg shot out into more numerous and better formed crystals than in the southern leg, where, in fact, the reduced silver immediately mingled with the mercury. Upon placing the legs of the tube east and west the process of reduction went on much more slowly, and the reduced metal stood at an equal height in both legs. Murray made an experiment of the same sort, in which he placed iron wire in a weak solution of silver. So long as the iron wire had no magnetic polarity no silver was reduced, but as soon as a magnet was placed near it the reduction commenced. He also found the reduction most considerable at the north pole of the wire, which is in accord with the experiments of Hansteen and Maschmann. Lüdicke placed concentrated saline solutions in a glass vessel over the two poles of an electro-magnet. He employed acetate of lead, muriate of ammonia, or photo-sulphate of iron. When crystallisation had taken place, it appeared that there was a clear round space left vacant between the two poles where the magnetic force was strongest, though the rest of the bottom of the vessel was uniformly covered with crystals.

ELECTRICAL EXHIBITION AT NEW YORK.—Preparations, says the *Electrical World*, for the Electrical Exhibition of the New York Electrical Society are now going on on all sides, and before the month is out a very creditable display will be laid before the public of New York, where nothing of the kind has ever been attempted before. This year, the semi-centennial of the completion of Morse's first telegraph instrument, is well chosen for the exhibit, and the timeliness as well as the enterprise of the society has been very generally appreciated. At the present time over 18,000 square feet of floor space has been allotted, and this will be covered by exhibits in every branch of electrical industry, contributed by over twenty-five of the leading electrical companies and by a great number of other concerns well known in their respective lines. As already announced by the society, there will also be a loan collection of relics and historical apparatus. Altogether the exhibition promises to be very interesting, and to do much to further electrical science and industry. The society has had no other object than the general good in this effort, which has been in contemplation nearly two years, and it should receive every encouragement in its work. We may add to this that Prof. G. Forbes, F.R.S., is, we believe, on his way to America with a view to exhibit his beautiful meter, first described in England at the late meeting of the British Association at Manchester.

BOARD OF TRADE LICENSES.—A special meeting of the Liverpool Council was held on Wednesday to consider, and, if thought expedient, to approve of the mayor, aldermen, and citizens of the city of Liverpool, acting by the council as the local authority under the Electric Lighting Act, 1882, consenting to the Liverpool Electric Supply Company (Limited) making an application to the Board of Trade for a license to supply electricity for public and private purposes within certain parts of the city, subject to such conditions as the council may prescribe; and also to consider, and, if thought expedient, to approve of the draft license, and to prescribe the conditions contained therein as the conditions upon which the consent of the council is given to the application for a license by the company. The council was also asked:—To consider, and, if thought expedient, to approve of the intention to make application, and of such application to the Board of Trade by the mayor, aldermen, and citizens of the city of Liverpool, acting by the council as the local authority under the Tramways Act, 1870, for a provisional order to enable the Corporation to authorise the use of steam or other mechanical power on the tramways constructed under the Liverpool Tramways Act, 1868, and the Liverpool Tramways Act, 1871; also to consider, and, if thought expedient, to approve of a memorial by the council to the Board of Trade for a provisional order to enable the Corporation to authorise the use of steam or other mechanical power on the tramways constructed under the Liverpool Tramways Act, 1868, and the Liverpool Tramways Act, 1871.

ELECTRIC LIGHTING FOR THE CITY OF DUBLIN.—The committee appointed last May by the Corporation of Dublin to inquire into the possibility of using the water-power at Island Bridge for the purpose of lighting the city by electricity has just issued its report. It is chiefly taken up with reports from experts to whom the committee referred the several points involved in the investigation. Mr. Spencer Harty, the city engineer, states that the condition of the mill race at Island Bridge is very neglected, and would require to be cleared; but that there is even now an average mean velocity of 72·5ft. per minute, and a fall of 11·57ft. and 6·32ft. at low and high water respectively, the effective power being 52 horse-power and 27 horse-power. By altering one of the sluices on a later occasion an effective power of 98 horse-power and 50 horse-power at low and high water was obtainable. On the 16th August Mr. E. Manville, electrical engineer of the United Electrical Engineering Company, Lambeth, London, reported upon the electrical part of the scheme. Relying upon a constant water-power of never less than 50 horse-power it was sufficient to produce current for 45 lamps, each of 1,000 candle-power. He estimates that the plant required will cost £4,134, which includes nine and a-half miles of lead covered main for two double circuits; and the annual maintenance at £1,175. If the mains are laid underground in bitumen cases the extra cost will be £460, and maintenance increased by £50 per annum. After consultation with the law agent in reference to the terms of the Electric Lighting Act, the committee recommend that the scheme submitted by Mr. Manville be adopted.

EDISON'S NEW LABORATORY.—Menlo Park has obtained world-wide fame from its being the residence of Edison during his labours on electric light matters. Now Llewellyn Park at Orange, N.J., will probably form one of the centres of electrical development. Here Edison is having built a laboratory the equivalent of which will hardly be found on this planet. The main building is 250ft. long, 50ft. wide, and three stories high. The lower story may be termed the machine shop. The second story will provide a grinding and polishing department, photographic rooms, and drawing offices. The tools in the machine shop are to be driven by a 40 horse-power engine. The energy required upon the second floor will be obtained electrically. The upper story is to be devoted to more delicate apparatus, principally electrical. In an annexe to the main building will be three Babcock boilers of 75 horse-power each. There will be two of Armington and Sims' high speed engines, and four dynamos driven by those engines. In addition to the main building and its annexes, there are four other buildings each 100ft. long, 25ft. wide, and 16ft. high. One of these buildings is to be devoted to galvanometrical work, and in it the use of iron has been carefully avoided, the nails being of

Digitized by Google

copper and brass, the tubes lead and copper, and the hinges, locks, window fasteners, &c., of non-magnetic material. In this building there will be seven piers of solid stone, entirely detached from the walls and the building, each being provided with a slate top having a covering of vulcanized hard rubber an inch thick. There will also be two large piers on a level with the floor 15ft. long and 8ft. wide. The second smaller building is to be a complete chemical laboratory. The third building will form partly a store room and partly a carpenters' shop. The last of these isolated buildings will be devoted to metallurgy.

TELEGRAPHIC COMMUNICATION WITH PARIS.—The French *Journal des Chambres de Commerce* has published some statistics relating to the French telegraph system, from which it appears that Paris has the following telegraphic communication with the rest of Europe :—Twelve lines to London, besides two from Marseilles to London having connections with Paris ; ten lines to Germany, of which four are with Berlin, two with Frankfort, and one each with Hamburg, Strasbourg, Cologne, and Mulhouse. Metz has no telegraphic communication with Paris. There are three lines with Austria, viz., two to Vienna and one to Bregenz. With other countries Paris has the following communications :—Belgium four, viz., two to Brussels and two to Antwerp ; Denmark one, viz., the submarine cable, Frédéricia-Calais ; Spain one, viz., to Madrid ; Holland two, both to Amsterdam ; Italy six, viz., two to Rome and one each to Florence, Turin, Genoa, and Milan ; Switzerland four, viz., two to Geneva, one to Basle, and one to Berne. As regards telegraphic communication with the provincial towns of France, Paris has six lines to Marseilles, four lines each to Bordeaux and Lyons, three each to Lille, Havre, Brest, and Toulouse, and two each to Amiens, Montpellier, and Nantes. All the other prefectures have one direct line to Paris, except Tulle, Quimper, Mont-de-Marsan, Foix, Carcassonne, Privas, Gap, Digne, Mende and Ajaccio, and these, it is said, are all to be placed in direct communication with the capital before long. The *Bulletin International de l'Electricité* says that the Conseil Général du Rhône has voted the establishment of telegraph lines placing Lyons in communication with Marseilles, St. Etienne, and Paris. The same paper states that a bronze line has been placed between Frankfort and Brussels. This line, which is for the present appropriated for the telegraphs, is destined eventually for the telephone service which is to be shortly established between Verviers and Aix-la-Chapelle, and later on between the Bourses of Frankfort and Brussels.

ELECTRIC LOCOMOTION.—On Saturday last a small number of gentlemen representing America and the Australian Colonies accepted the invitation of Lord Bury, the chairman of the Electric Car Company, to inspect the experimental electrical car running between Shoreham and West Brighton. Starting from Shoreham the visitors were run in the electrically-propelled car to Southwick, says the *Daily Telegraph*, at the rate of about twelve miles an hour ; then, as a further illustration of the principle, a heavily-weighted traction car, similarly propelled, was run towards Shoreham at a speed of from fifteen to twenty miles an hour ; and finally there was a smart trip to West Brighton. The car carries eighty cells stowed beneath the seats, and, as with the motor and the gearing beneath, all the apparatus is out of sight. Briefly, it may be said that starting and stopping are effected as rapidly as could be done with any conceivable species of traction. On these points the visitors on Saturday expressed themselves completely satisfied ; but the inspection was made with the eminently practical view of discovering not only the efficiency of the apparatus, but its comparative cost, and upon these points Lord Bury himself technically entered into careful explanations, stating what he considered were the conditions of the problem. At the present time horses and steam on tramways cost 6d. per car-mile. This, his Lordship said, they had taken as their basis, and they were actually running at 4d. per mile. The engineers stated the cost at even less. In order to be on the safe side, he would not pledge himself to 4d., but he would assert that they could run at less than 6d., and that every improvement in motor or accumulator would be so much to the good. The Immisch motor, to which much of their success was due, was within 3 per cent. of theoretic perfection, and therefore they could not expect much advance upon that ; on the other hand, the accumulators would admit of amendment in some particulars. He claimed, as a net result, that working on a bad line, with a gradient amounting to one in twenty, they had yet come considerably below the cost of horse or steam power.

TECHNICAL EDUCATION.—The sixtieth annual meeting of the German Natural Philosophers and Doctors of Medicine—the equivalent to our British Association for the Advancement of Science—took place last week at Wiesbaden, when Prof. Dr. Preyer, of Jena, read a paper entitled "Natural Philosophy and School," which was cordially received and enthusiastically cheered at its conclusion. The Professor condemned entirely the present German methods of teaching in the higher schools, as well as much of what is taught. He says there must be less sitting on benches and being crammed with a lot of subjects that are of little use except for a certain few ; that nature and practical objects must be more studied, there must be more activity out of school ; that for a maximum of time spent a minimum of value is received ; that the scholars about to matriculate for the University are devoid of practical sense, have no confidence in their judgment, have acquired no manual accomplishments ; and says a great deal more besides. This is by no means the first time all this has been brought before the public. Last winter a professor of one of the first technical colleges gave three lectures on the same subject, and put it even more forcibly that education should be more practical and less theoretical. Again, a week or two ago a leading industrial paper was praising the introduction of examinations, such as some college in England had lately published, as just what Germany had been striving to obtain for years past, and much regretting that they were behind us in this particular. When this is all put together, it leads to the idea that, as Germany is becoming more and more an industrial country, it requires a more practical method of schooling for its members ; and who can say, as time flows on, whether in the end the teaching in Germany and the Continent generally will not descend to practical methods not dissimilar to our own, which have grown up as practical necessity demanded ? If so, which is very probable, does it not behove us to keep such technical education as we have at present, and to be cautious, instead of rushing in for new schemes as proposed by the late Bill, which may turn out in the end to become similar to what they are trying to get rid of on the Continent ? If our attention were turned to giving the lower and lower middle-classes a more thorough, better, and broader education, it would do more towards assisting us to compete with other nations than a new scheme of technical education, which, as far as engineers—and that is a wide field—goes, is scarcely required ; but if anything should be wanting, it could be easily accomplished without a cumbersome Act of Parliament. —*Engineer.*

THE PRACTICE OF DYNAMO DESIGN.

BY GUY C. FRICKER.

(Continued from page 340.)

In disc ring dynamos of the Gülcher and "Victoria" type the radial depth of the core is necessarily much smaller than in bi-polar machines, in order to permit of the introduction of the extra poles without any undue leakage of the lines of force from one to the other. It can be shown that in these as well as in machines of any other class that the greater the radial depth the smaller will the weight of the armature become, both in iron and copper. The armature is, however, but a fraction of the total mass, and it must be remembered that the section of the field-magnet cores will increase with that of the armature, and, after a certain point has been reached, in a quicker ratio than that in which their length will diminish. Without attempting here to deal analytically with this point we will fix the ratio quantities in accordance with those proportions which in the author's experience have been found most satisfactory in practice.

The list of quantities for a machine giving the same output as before will be as follows:—

$p = \cdot4$	$M = 20$
$q = \cdot4$	$\gamma = \cdot65$
$\beta = \cdot04$	$\mu = \cdot6$
$\rho = 1$	$P = 4$

With regard to γ, it must be remarked that since the core has now to be laminated in two directions, a far greater proportion of the total space is unoccupied by iron; the coefficient has thus to be diminished accordingly. μ is also necessarily smaller, since the armature winding is now divided into four parallel circuits instead of two, and is therefore of less section. This characteristic in multipolar machines renders them peculiarly fitting for all purposes where very heavy currents are required, when in bi-polar machines the copper must needs be so massive as to cause the generation of serious eddy currents within itself, to say nothing of the difficulties in winding.

From equation 4 we have

$$R = 3\cdot6 \times 2\cdot08 = 7\cdot49, \text{ say } R = 7\tfrac{1}{2}\text{in.}$$
$$N = 502$$
$$A = \cdot00566.$$

The depth of copper $\mu\beta R = \cdot18$in.; this divided into three layers gives the section as ·06in. × ·094in. wide, from which we find

$$\mu = \frac{\cdot094}{\cdot094 + \cdot05} = \cdot65.$$

This figure is about 9 per cent. higher than that assumed, but the error is on the right side; it is therefore scarcely worth while to make an alteration in the radius, for which a convenient working value has already been determined.

The number of parts in the commutator must be a multiple of 4, since there are 4 poles. There must also be two adjacent sections of winding to each segment of the commutator, because the coil has to be begun from the centre of the length of strip and wound in opposite directions on either side so as to finish with both ends outside. Further, there are to be three layers in each section of coils. The total number of coils must thus be a multiple of 24, and N is therefore adjusted to 504. This will give 84 parts in the commutator.

The total number of lines passing through the armature are—

$$Z = \frac{117 \times 10^6}{504 \times 1000} = 232$$

But since in machines of this build there are two parallel magnetic circuits in the external field as well as through the armature, it will simplify matters to deal with one of these circuits only throughout. The number of lines which will be considered is thus 116, and the path through which they have to pass is one half the section, and also one-half the length of that in a two-pole arrangement; the resistance R_A thus stands as before, and is

$$\frac{\pi\left(R - \frac{pR}{2}\right)}{pq\gamma R^2} = 3\cdot22,$$

which multiplied by the saturation coefficient 2·45 = 7·9. The air gap $\delta = \beta R + \cdot156 = \cdot456$in.; this figure we will convert into ·5in. A convenient angle for the pole shoe is $\frac{2\pi}{7}$, and remembering that one-half the surface of the shoe only is to be considered in the single circuit, we find the area to be

$$\frac{\pi}{7} R^2 (q + 2p - p^2) = 26\cdot3,$$

and the resistance R_a is $\frac{1440}{26\cdot3} = 54\cdot5$, which added to the armature resistance is 62·4; thus $p_1 = 116 \times 62\cdot4 = 7{,}250$. The numerator constant in the resistance ρ for this type of machine may be taken as 1,300; the value of ρ is thus $\frac{1300}{15} = 86\cdot5$, and the waste lines are $\zeta = \frac{7\cdot250}{86\cdot5} = 84$. One half of these lines only are supplied from the single circuit which we are considering, thus Z_2 must be taken as $116 + 42 = 158$. The section of the field cores must thus be $\frac{158}{18 \times \cdot8} = 11$ sq. in., for which a circular bar 3·75in. in diameter would be used.

The depth of winding on the exciting coils will be $\frac{3\cdot75}{4} = \cdot937$, say 1in.; giving the length of a mean convolution as 15in.

In multipolar machines it is usual to connect the series part of the winding on the several bobbins in parallel, or, at least, to make a multiple-series connection. The arrangement is often modified in similar machines under different circumstances. The average section of wire in the whole winding will not, however, be much affected by the arrangement of the series-winding, since the latter bears a considerably smaller proportion to the total winding than does the shunt, which is unaffected.

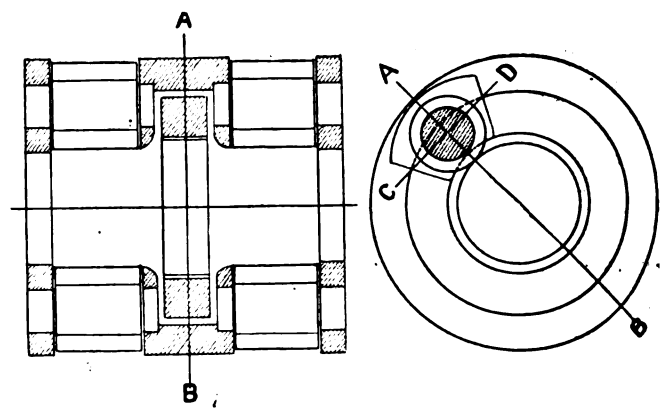

FIG. 16.

In making the rough calculation for the length of the cores we will suppose the average current to be 5 amperes only, instead of 7, in order to allow for the required lattitude in μ_1, which we will first assume as ·65. The number of watts dissipated per linear inch of core is $3\cdot75\pi = 11\cdot8$; we thus find the average value of A to be ·00289, the corresponding circular wire to which is ·0606in., giving

$$\mu_1 = \cdot885 \times \frac{\cdot0606}{\cdot0606 + \cdot02} = \cdot664$$

The number of turns per inch is $n = \frac{\mu_1^2 d}{A} = 152$, and allowing 2,000 ampere turns for the external circuit we have $\frac{7250 + 2000}{152 \times 5} = 12\cdot15$in. for the total winding, say 6¼in. outside measurement for each bobbin. In Fig. 16 the above dimensions are drawn out. It will be observed that the axis of the field-magnets is above the centre of the section of the armature ring; this is necessary in order to get sufficient strength at the junction of the magnet bar with the pole shoe. A good rule to adopt is to find the centre of the magnet bar on the chord C D, as shown in the figure. The mean radius of the frame in the

Digitized by Google

present case is 7in. The depth of the frame is most suitably made slightly greater than the outside diameter of the exciting bobbin, which is here 5·75in.; the frame is therefore made 6in. deep. Since cast iron has a much lower specific magnetic conductivity than wrought iron, its section in the magnetic circuit must be proportionately increased. In practice it is found that ordinary samples of cast iron can most safely be considered as having but one half the conductivity of soft wrought iron; thus, since the lines divide into two branches on entering the frame, the section of the latter must be equal to that of the magnet bar, viz., 11in.* The thickness will be $\frac{11}{6} = 1{\cdot}83$, say 1⅞in. The total length of the external circuit, allowing for the thickness of the pole-shoes, is 26½in.; the resistance R_F is thus $\frac{2 \times 26{\cdot}5}{11} = 4{\cdot}83$, and $K_2 R_F = 4{\cdot}83 \times 2{\cdot}45 = 11{\cdot}83$, which gives $p_2 = 11{\cdot}83 \times 158 = 1{,}870$, and $P = 7{,}250 + 1{,}870 = 9{,}120$.

The weights will be as follows:—

Armature core	62 lbs.
Magnet cores	155 „
Frame sides.....	260 „
Pole-shoes, say	80 „
Armature winding	12 „
Field-magnet „	104 „

The total weights of the various materials being—

Wrought iron.....	217 lbs.
Cast „	340 „
Copper	116 „

The resistance of the armature is ·045 ohm, thus the loss in watts is 450.

The loss in the magnets will be 590 watts, whence the electrical efficiency is $\frac{10000}{10000 + 1010} = 91$ per cent. nearly.

An examination of these three designs will show that as electrical instruments there is very little to choose between them. The drum armature is the most efficient, but it is also the heaviest, whilst the multipolar ring machine is the lightest of all, but also the least efficient. Considered from an engineering point of view, the 4-pole arrangement certainly appears to be the best, chiefly on account of the superior accessibility of the armature coils and also for its splendid ventilating properties. In these respects the drum arrangement is as certainly the worst.

REINFORCING ELECTRICAL CONTACTS TO INCREASE THEIR RELIABILITY,†

WITH EXAMPLE OF APPLICATION TO REELING SILK FROM THE COCOON.

BY E. W. SERRELL, JUN., NEW YORK.

The object of the paper is to explain a method of securing a good electric contact under circumstances in which ordinary solid or mercury contacts will not work.

The method consists in the use of a sucking coil or small electro-magnet, placed near the contact and traversed by the whole or a part of the current when the circuit is closed. When the contacts touch, no matter how lightly or imperfectly, the magnet or coil is excited and acts on an armature in such manner as to cause the parts of the contact to be drawn more firmly together and to scrape over one another so as to be cleaned by a mechanical action produced by the current itself every time that contact is made. By this method all the difficulties commonly experienced in the use of electric contacts may be overcome. If the parts are made to touch even in the slightest degree a thoroughly good contact is instantly secured.

The method is applicable to signalling apparatus and many other purposes, and is already used with success by the inventor in automatic machinery for reeling silk from the cocoon. By its use contacts have worked reliably for very long periods under circumstances which would give rise to insuperable difficulties without it.

Its application to automatic machinery for reeling silk from the cocoon was explained. This machinery has created a new industry, all silk having hitherto been reeled by hand.

The use of electrical appliances for reeling silk is greatly facilitated by the employment of this device, and is leading to important results; and the inventor considers that, as by this means a perfectly reliable contact is easily obtained, the use of electricity for controlling textile and other machinery may be very greatly and advantageously extended, especially in all cases in which light contacts must be used.

* Care must be taken to secure the full magnetic conductivity at the junctions of wrought and cast iron.

† Abstract of a Paper read before the British Association Meeting at Manchester, September, 1887.

THE LATE MR. O. E. WOODHOUSE.

By the death of the senior partner of the firm of Woodhouse and Rawson, which it was our painful duty to briefly notify in our last week's issue, the electrical world has lost one of its most enterprising and practical engineers. The melancholy event, which took place on the 21st inst., at Brighton, whither the deceased gentleman had gone to recruit his exhausted energies, was not altogether unexpected, for he had been suffering for a period of two years from the strain of overwork, intensified no doubt by the protracted litigation in which his firm was involved with the Edison and Swan Company towards the end of 1885. At that time, feeling that his strength was giving way, Mr. Woodhouse, acting under the advice of his physician, left England for a short residence in Cannes, where he had the misfortune to contract a fever, from the effects of which he never wholly recovered, and to which in a great measure his premature demise must be ascribed.

Mr. Woodhouse was a native of London, where he was born on the 21st October, 1855. He received his elementary education at Marlborough College, from which he proceeded to King's College, London, where he acquired that knowledge of physical science which stood him in such good stead in his subsequent career as a practical electrician and engineer. From King's College he passed directly to the workshop of Messrs. Hunter and English, the well-known engineers of Bow, with whom he spent three years, principally in their fitting department. In August, 1877, he entered the service of the Great Eastern Railway Company under Mr. W. Adams, the locomotive superintendent, with whom he formed so close a friendship that when Mr. Adams accepted a similar position in the service of the London and South Western Railway Company Mr. Woodhouse elected to follow the fortunes of his chief, and transferred his services to the workshop of that company, where he remained until the beginning of 1881. In July of 1880, Mr. Woodhouse made a journey to America with Mr. J. C. Peache, assistant to the London and North Western Railway Company's locomotive department at Crewe, and spent six months in inspecting the principal engineering and general scientific works both in the United States and Canada, from which he learned many of those practical lessons in engineering which he turned to such good account on his return to England towards the close of that year. Shortly afterwards—in 1881—he entered into partnership with Mr. F. L. Rawson, under the title of Woodhouse and Rawson, and to his great energy and ability was due in a great measure the world-wide reputation which the firm have acquired as electrical engineers. Notwithstanding the many claims which his business had upon his time, the deceased still found leisure to cultivate some of the amenities of life, and, as is well known, was a keen votary of athletic sports. His funeral, which took place at Kensal Green Cemetery, on Monday last, was largely attended by his personal friends and the *employés* of the firm, a fitting tribute to the memory of one who as an associate and master had by his many sterling qualities earned the esteem of all who came in contact with him.

THE POSTMASTER-GENERAL'S ANNUAL REPORT.

It may be due to natural curiosity in respect to one particular branch of the Post Office, but our impression after a careful examination of the POSTMASTER-GENERAL'S Annual Report just published is, that the familiar little Blue Book for the year ended 1886-7 is fuller than usual of details we did not want, and emptier than usual of information we had a right to expect. On its own merits we should have thought that the Post Office Telegraph was at least as important a branch of the Post Office as, say, Post Office Annuities and Life Insurance, or the issue of Licenses for Dogs, Armorial Bearings, and Hackney Carriages, by the same Department. But either this is not the view of the POSTMASTER-GENERAL, or else the head of each Branch is allowed just as much space as the importance of his business, in his own estimation, may seem to demand. If this latter be the correct explanation of the paucity of information relating to the telegraphs contained in the present Report, the persons responsible for it must be exceptionally modest, and will not be surprised that they are taken at their own measure. The way in which they are classified in the table of superior officers (page 25) might satisfy the humblest of mortals. Amongst the 42 superior officers in the metropolis just three are included who belong to the Telegraph Service. There is, for example, one male Engineer-in-Chief, who, if we mistake not, is the engineering head of the telegraph service of the whole United Kingdom. There is also one Female Medical Officer, whose functions, whatever else they may be, are certainly not telegraphic. But she is a "superior" officer of the Post Office, and, as such, apparently counts for just as much as an Engineer-in-Chief of British Telegraphs. On the same principle, we are told to an ounce the weight of correspondence carried for other than Post Office Departments; but we can learn nothing as to the present average length of telegrams, or the speed of their despatch and delivery now that they are so much more numerous than formerly. Nor are we in any way helped to a conjecture as to the financial prospect of the experiment which provokes these inquiries.

That the reduced tariff which came into operation on the 1st October, 1885, has been a great success so far as increase of traffic is concerned can hardly be gainsaid. Whether it has been equally satisfactory from the revenue point of view may be doubted from the little that is said about that aspect of the question in the Report. We hesitate to quote exact figures in this relation, for the tables, which seem to have been framed by different hands, show different results according as we include or exclude this or that item of Receipts or Expenditure. But roughly it may be gathered that while the business and the income go on increasing, so does the deficit. Between the Receipts for 1885-6 and 1886-7 there is a difference of, roughly, £100,000 in favour of the later year; and there is almost the same difference of expenditure in favour of the former. It is too early to make predictions, but it is obvious that if this course of things continues the annual deficit will in due time overtake the Receipts, unless, indeed, the Expenditure becomes stationary, which is unlikely, and the Receipts increase at their present rate, which is highly improbable. This is not a very cheering prospect, and perhaps it may account for the POSTMASTER-GENERAL'S brevity and reticence in regard to the Telegraph Service generally. No useful comparison between two whole years can be made, because the first half of 1885 was worked under the shilling rate; but during the closing halves of 1885-6 and 1886-7 respectively, both under the sixpenny rate, the increase of messages was at the rate of 14 per cent., the increase in payments being 13 per cent. The exact figures are 19,071,782 against 16,737,837, and £641,709 against £566,039. The interest on the original capital expended for the purchase of the Telegraphs, amounting to £326,417, constitutes a permanent charge equal to nearly one-fifth of their present income. A few years ago, in 1880-1, this charge was almost met by the net revenue, the deficit being only £984; but since then the deficit has rapidly increased, the balance between Receipts and Expenditure being less and less every year. In the face of this fact the tariff was reduced in 1885, with a then deficit of £36,350 in excess of the permanent charge, and to-day it amounts to £469,840, or £143,423 in excess. In other words, the Telegraph revenue would be the last-named amount to the bad, even if interest on the original outlay were wiped off.

For the purpose of ascertaining the effect of the reduced rate on the number of messages a comparison may be made between the two periods, April to September, in the years 1885 and 1886; and according to our calculation the increase in the latter half year was 8,362,226, or at the rate of, say, 16 millions for the whole year. This, on a total of about 40 millions, excluding foreign press and other messages not affected by the reduced tariff, is highly gratifying to the promoters of cheap telegraphy, and we may leave the figures for them to make the most of. If we could be at all sanguine that a comparison between two whole years of sixpenny telegrams will show a rapidly growing revenue and even a slow diminution of expenditure we might share their satisfaction. At present the condition of affairs appears to be that with an enormous development of traffic the necessary outlay in dealing with it is not less enormous, and that consequently we are enjoying cheap telegraphy at the expense of the taxpayer, which is precisely what we have all along foretold. No extensions of unusual magnitude are mentioned in the POSTMASTER-GENERAL'S Report, and we are led to infer that the additional expenditure is incurred chiefly by extra working expenses; and if that be the case there is every apparent

Digitized by Google

likelihood of their increasing as the traffic goes on enlarging. A new line has been erected to North Wales, and a fresh cable laid from thence to Ireland, at a cost of £40,700. New telegraph offices have been opened also at 232 post offices. These facts show that the Post Office Telegraph Department is adequately meeting the demands which a popular tariff necessarily creates. But it cannot be supposed that these demands will diminish, or that the efforts to meet them will be allowed to slacken. Some allowance in the year reported upon must, of course, be made for the expenditure entailed in repairing and renewing wires broken down last winter by a snowstorm of almost unprecedented destructiveness; but to meet such contingencies in future the popular cry is for greater immunity, and this, of course, means increased outlay at no distant date. On the whole, although the public who are customers of the Telegraph may be congratulated on possessing the cheapest and most efficient service in the world, the country is not to be complimented on the precipitancy with which the cheapening was accomplished.

CORRESPONDENCE.

SPRINGS ON TELEGRAPH WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reporting the discussion on Mr. Preece's paper read at the British Association meeting, you say that I spoke of practical objections to Sir F. Bramwell's suggestion of the use of a spring at every telegraph post. The vague assertion that there are "practical objections" to an untried invention is very easily made, and usually leads to no loss of reputation when disproved in actual working. I said at the time that the suggestion was very ingenious, and would be satisfactory only for the size of spring required. The cost of the new fitting must, in any case, be considerable, and although even a small spring must do some good, it ought not to be introduced unless the good it does is commensurate with its cost. When the tension in a telegraph wire increases, the wire increases in length in consequence, and it is on this account that the increased dip of a telegraph wire in summer does not follow the formula usually given connecting temperature of the wire and dip, or rather, the summer temperature of a wire is usually much higher than it is assumed to be in the calculations of telegraph line men. We all know, then, that the actual extension of the wire due to stress introduces an important regulating effect.

By calculation it may be shown that if there is a tensile stress of $\frac{1}{4}$ of the breaking stress in a telegraph wire due to its own weight, then a total load of more than three times (and not merely twice, as it would be but for the extension of the wire) the original load is needed to produce twice the stress, or half the breaking stress. So great is this regulating effect that the compensation springs designed by me for use at the heads of posts in telpherage and other contrivances for the same purpose have proved to be unnecessary.

Let us assume that Sir Fred. Bramwell's spring is at least large enough to introduce as much of a regulating effect as the extension of the wire itself. I take it that this is the least amount of regulation for which it is worth while to introduce the new fitting. In an iron wire 300ft. long, if the stress changes from 12,500 to 8,333lb. per square inch, it shortens 0·52in. If the iron wire was No. 7½ we therefore want a steel spring whose highest working load is, say, 270lb., and which shortens by 0·52in. when the load becomes 180lb. That is, a steel spring is required at every post which will work up to a pull of 270lb., with an extension of 1·56in. Its proof load would be 540lb., with an extension of 3·12in., so that a resilience of $\frac{540 \times 3{\cdot}12}{12 \times 2}$, or 70 foot-pounds, is required.

The resilience or the energy which may be stored up in a spring before it takes a permanent set is, for a given material, simply proportional to the weight of the spring, and does not depend on the size of the coils or of the rod or wire of which the spring is made. I find that the steel spring required to introduce as much compensation as is already introduced by the elasticity of the wire itself would weigh about 4lb., taking 50,000lb. per square inch as the proof shear stress of the material of the spring. I have here assumed a breaking shear stress of 100,000lb., or nearly 50 tons per square inch in the material of the spring, and if this is regarded as too high, the weight of the necessary spring at the top of each telegraph post for each telegraph wire must be increased. The weight of the spring is nearly inversely as the square of the proof stress (or stress which would produce permanent set). If the proof stress is taken to be only half what I have chosen, the weight of each spring for each iron telegraph wire on each pole would be more than 16lb., and this would only introduce as much of a regulating effect as the elastic yielding of the wire itself already introduces. At the B.A. meeting I thought that some such weight of steel in the spring as 10lb. or 12lb. must be assumed, but I knew quite well that experiment on an actual line was the only method of settling the question. If steel springs can be manufactured which shall with perfect certainty take no set for shear stresses of 50 tons per square inch my "practical objection" to Sir Frederick Bramwell's suggestion disappears, as the weight of each spring would then only be slightly in excess of 11lb.—

Yours, &c.,

JOHN PERRY.

10, Penywern-road, S.W., Sept. 19, 1887.

FORMULÆ FOR SELF-REGULATING DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: That the formulæ usually given for the compounding of self-regulating dynamos are not sufficiently accurate for practical use was shown in two articles I wrote for *The Electrician* in 1885.* These formulæ are based on the assumption that the strength of magnetic field is throughout proportional to the exciting current for the whole range of the shunt and series excitement, a condition which, needless to say, does not obtain in practice. The magnets being partially saturated before the series coils begin to act, a greater number of series turns is required than the formulæ would lead us to suppose, the mean value of each ampere turn in adding to the E.M.F. being much less than the mean value of each ampere turn of shunt wire.

Although we do not expect the formulæ to give accurate results with such an assumption underlying them, still the partial saturation of the magnets by the shunt scarcely accounts for the discrepancy manifested, a discrepancy due, I believe, to the weakening of the field by the armature current and to the counter E.M.F. set up by self-induction. On this account the E.M.F. added by the series coils is altered when the factors making up a constant product of ampere turns and speed vary, even when in machines of similar size the magnets are saturated to the same degree by the shunt coil.

The proportion of excitement furnished by the series wires varies not only in machines by different makers but in different machines by the same makers according to the purpose for which they are designed, and depending largely on the relation of weight to output. In machines having a large number of turns on the armature and giving a large output for their weight the series winding may furnish one-half of the total excitement, whereas in machines with few turns on the armature, weighty but more efficient, the series wire may furnish but one-fifth of the total. If we imagine that the series wire gives at full load a field strength equal to one-tenth of that given by the shunt, then in the first machine, where half the excitement is furnished by the series, the mean value of each ampere-turn of the latter is ·10 that of each ampere-turn of the shunt; while in the case of the machine where one-fifth is supplied by the series the mean value is ·40. To put it in other words, the number of series turns given by the formulæ would require to be multiplied in the first instance by 10, and in the second instance by 2·5, the former number being the highest coefficient I have known.

In every size of Phœnix machine the ratio between the ampere turns furnished by the series wire and the ampere

* "Note on the Regulation of Dynamos, Vol. XV., pp. 59, 89

Digitized by Google

turns on the armature is the same, whatever be the speed or E.M.F., the shunt coiling being such as to secure under these conditions proper regulation. A difference is made only in special cases where the characteristic is required to rise considerably, or where an alternative winding for charging accumulators is required.—Yours, &c., W. B. ESSON.

London, Sept. 26th, 1887.

ELECTRICAL DISTRIBUTION BY ALTERNATING CURRENTS AND TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your reviewer of my little pamphlet refers to my experiments with induction coils in 1883, and states that these experiments were made with series transformers. That is true so far as the experiments designed to prove the existence of the detrimental counter-electromotive force in the series system was concerned. The experiments were made and described to prove that induction coils, as patented and employed in series order of distribution by Jablochkoff, Gaulard-Gibbs, and others, could not succeed, for the simple reason that the consumers would all be dependent on each other, and that the opposing forces in the primary increase as work in the secondary decreases, a condition which was obviously diametrically opposite to that required for a successful series system.

I do not assert that the series system is an impossibility; what I asserted, and still assert, is that no series system yet patented can possibly distribute successfully.

The systems described in the specifications prior to 1883 are all series systems; they might partially succeed in a limited distribution system by using transformers with over saturated cores, but the number of lamps on each transformer would require to be small, and then connected in series, and it could be shown that the economy of such a system would be under 50 per cent.; and I maintain that that is the best that can be done with the Jablochkoff or any other early system, even with the aid of all the knowledge and experience now to be found on the subject.

And, considering the claims made by the owners of these early patents, any inventor who may have an improvement which might make a success of the series system, had better keep it to himself; if there is any money behind these owners they will adopt his improvements, and very likely call him an infringer of Jablochkoff's patent.

The experiments which proved to me the self-regulation in the parallel system were made with mains at 1,000 volts, so that I can hardly be said *to have overlooked the possibility of using high tension mains*, as stated by your reviewer.

My remark about the size of the wires is not so far from the mark, as very little over 2,000 volts can yet be used over any system. At the date of my writing 1,000 volts was a high pressure, and at that pressure I guess the size of the conductors for a distribution of, say, 100,000, 16 candle-power lamps would still truly be "prodigious," and that number of lamps is not large when talking of lighting towns and cities, as the promoters of electric lighting were then doing.

Referring to Messrs. Manville and Madgen's letter, I can only say that Jablochkoff's specification describes and claims the series system of distribution by induction coils. The patent is for a combination of old and well known apparatus combined together in a *particular method* for distribution of electric lights. The combination consists of an alternating or intermittent current generator with a metallic or conducting wire circuit and induction coils placed in series order, and these induction coils supply current to lamps (shown also in series order).

The combination failed entirely to effect the purpose—*it would not distribute;* and although it was afterwards taken up by at least half-a-dozen subsequent inventors during the ten years following the date of the invention, none of them succeeded with it. The *secondary circuits are not independent of each other electrically, and neither primary nor secondary circuit is self-regulating.*

Neither is the combination new. A patent granted to C. W. Harrison, Woolwich, in 1857, describes the same combination; here we have a primary circuit in connection with an induction coil, and the induced current operates the light.

Jablochkoff's second claim is for a system "substantially as herein described" a series system, which does not contain a single one of the elements which are *essential* in the now successful system.

The "intelligent workman" test would settle this point easily. Put Jablochkoff's patent specification into the hands of an electrical engineer of ordinary skill, could he from that specification ascertain anything at all which would lead him to lay down a distribution plant containing the elements absolutely necessary for the succesful operation of the lights? Does the specification direct him to employ *high pressure* in the mains, *constant pressure* in the mains, *induction coils* with their *primaries connected in parallel* to the mains, induction coils with a certain ratio of reduction, induction coils with a certain amount of impedance? I trow not. The directions are to connect the primaries in series. The engineer would therefore conclude that a constant current and variable E.M.F. in his primary was the proper thing. He would set up a constant current dynamo and place his coils in series, and if he followed the specification further he would put his lamps in series also, and then he would find the whole arrangement a failure.—Yours, &c.,

Glasgow, Sept. 26, 1887. RANKIN KENNEDY.

BATTERY WANTED.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will any of our electricians kindly give me a description of a battery that will light 10 12-volt lamps four hours a day for one week with one charge? I have some porous pots 9in. by 3in. which I should like to use.—Yours, &c.,

J. BARTON.

309, Regent-street, London, W., Sept. 28th, 1887.

ON THE SPECIFIC RESISTANCE OF COMMERCIAL IRON.*

BY W. H. PREECE, F.R.S.

So many improvements have been made in the quality of iron supplied for telegraphic purposes that I was anxious to determine with great accuracy the specific resistance of that which is now used.

For this purpose a length of Swedish charcoal iron, carefully prepared, and similar to that used for the best iron telegraph wire, was drawn for me by Messrs. Frederick Smith and Co., of Halifax. The results were as follows:—

Test of 75 feet of Swedish iron wire, weight 2259·86 grains; diameter ·040 inch, or 40 mils. One foot of pure copper wire, d millimetres in diameter, has, according to Dr. Matthiessen, a resistance of $\frac{10{\cdot}323}{d^2}$ ohms at 60deg. F. Resistance of 75 feet of pure copper wire, 40 mils. in diameter, $= \frac{10{\cdot}323}{40 \times 40} \times 75 = {\cdot}4839\omega$. Now, by very careful measurement, the resistance of the Swedish iron wire $= 2{\cdot}920\omega$ at 60deg. F.; therefore, the relative resistances of copper and iron wires are as
